

CX-Supervisor Script Language

Notice

OMRON products are manufactured for use according to proper procedures by a qualified operator and only for the purposes described in this manual.

The following conventions are used to indicate and classify precautions in this manual. Always heed the information provided in them. Failure to heed precautions can result in injury to people or damage to the product.

DANGER!	Indicates information that, if not heeded, is likely to result in loss of life or serious injury.
WARNING	Indicates information that, if not heeded, could possibly result in loss of life or serious injury.
Caution	Indicates information that, if not heeded, could result in relatively serious or minor injury, damage to the product, or faulty operation.

OMRON Product References

All OMRON products are capitalised in this manual. The word “Unit” is also capitalised when it refers to an OMRON product, regardless of whether or not it appears in the proper name of the product.

The abbreviation “PLC” means Programmable Logic Controller and is not used as an abbreviation for anything else.

Visual Aids

The following headings appear in the left column of the manual to help you locate different types of information.

Indicates information of particular interest for efficient and convenient operation of the product.

1, 2, 3... Indicates lists of one sort or another, such as procedures, checklists etc.

Represents a shortcut on the Toolbar to one of the options available on the menu of the same window.

All rights reserved. No part of this publication may be reproduced, stored in a retrieval system, or transmitted, in any form, or by any means, mechanical, electronic, photocopying, recording, or otherwise, without the prior written permission of OMRON.

All copyright and trademarks acknowledged.

No patent liability is assumed with respect to the use of the information contained herein. Moreover, because OMRON is constantly striving to improve its high-quality products, the information contained in this manual is subject to change without notice. Every precaution has been taken in the preparation of this manual. Nevertheless, OMRON assumes no responsibility for errors or omissions. Neither is any liability assumed for damages resulting from the use of the information contained in this publication.

About this Manual

This manual describes the script language syntax as a supplement to CX-Supervisor application user manual.

This manual contains the following:

- ◆ **Chapter 1 Introduction.** An overview to this manual including special typographical conventions.
- ◆ **Chapter 2 Expressions.** A description of the use of expressions within scripts.
- ◆ **Chapter 3 Scripts.** An introduction to scripts and the type of scripts.
- ◆ **Chapter 4 Functions and Methods.** A detailed reference to the CX-Supervisor script language.
- ◆ **Chapter 5 Script Examples.** A description of the script language in practice, using some examples.
- ◆ **Chapter 6 Colour Palette.** A description of the colour palette that can be applied to certain script statements.
- ◆ **Appendix A OPC Communications Control.** This appendix contains a list of the available component properties and gives details of the Visual Basic script interface.
- ◆ **Appendix B Lite Communications Control.** This appendix contains a list of the available component properties and gives details of the Visual Basic script interface.
- ◆ **Appendix C VBScript Features.** This appendix provides a summary of the VBScript features available for use with the ExecuteVBScript and ExecuteVBScriptFile script functions.
- ◆ **Appendix D Jscript Features.** This appendix provides a summary of the JScript features available for use with the ExecuteJScript and ExecuteJScriptFile script functions.

A **Glossary of Terms** and **Index** are also provided.

CHAPTER 1

Introduction

This reference manual describes the script language syntax as a supplement to the CX-Supervisor User Manual. It provides detailed definition of the syntax of CX-Supervisor scripts that drive project, page, object actions and CX-Supervisor expressions as used by objects and scripts.

Typographic conventions used in the examples in this reference manual are as follows:

- ◆ Script commands and reserved words are shown in the preferred case, which may be either lower-, upper- or mixed-case.
- ◆ Points are shown in lower-case. Objects are shown in upper-case.

The following terms are used in this reference manual:

- ◆ Application. A set of files, containing an executable file, that carry out certain tasks. This reference manual refers to the Microsoft Excel and Microsoft Word for Windows applications.
- ◆ Constant. A point or object within a script that takes only one specific value.
- ◆ Executable. A file that contains programs or commands, and has an '*.EXE' extension.
- ◆ Nesting. To incorporate one or more IF THEN ELSE/ELSEIF ENDIF statements inside a structure of the same kind.
- ◆ Operands. Constants or point variables.
- ◆ Operators. Relational, arithmetic, and logical statements, for instance '+', '<=' or 'AND'.
- ◆ Or ('|'). The '|' symbol is used to represent 'or', where there are two or more forms of the same syntax.
- ◆ Point Types. Either Boolean, Integer, Real or Text.
- ◆ Point Variable. A point or object within a script that may take different values.
- ◆ Strings. Data in the form of text delimited by quotation marks (" "), which can be assigned to a point.
- ◆ The '{' and '}' braces. Must be inserted around the argument command or an error is reported. An error is reported if there are spaces between braces.
- ◆ 'TRUE' and 'FALSE'. Refer exclusively to Boolean states, where Boolean state 0 is 'FALSE' and Boolean state 1 is 'TRUE'.

CHAPTER 2

Expressions

This chapter describes the use of expressions within scripts.

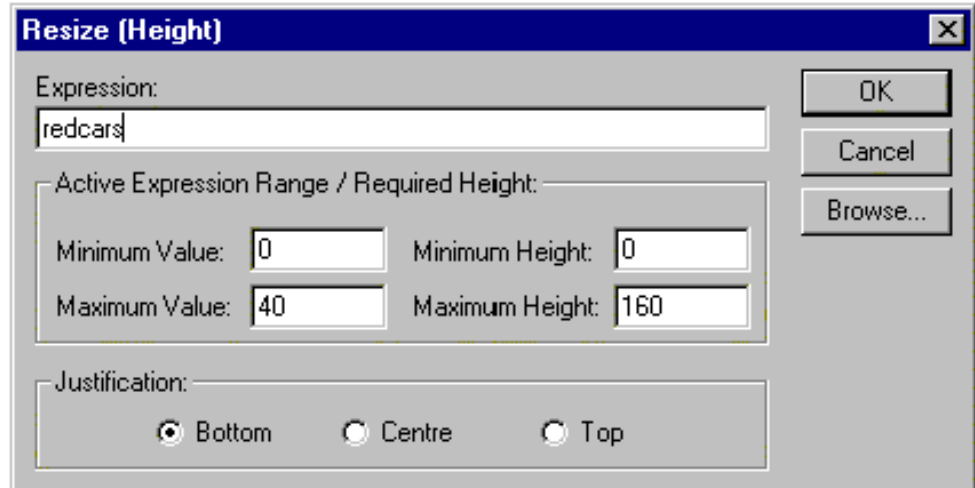

Expressions consist of operators and operands:

- ◆ Operators are relational, arithmetic, logical and include many functions.
- ◆ Operands are constants or point variables.

Expressions can be used in a script as part of a statement (refer to chapter 3, Scripts and chapter 4, Functions and Methods). However expressions can be applied to the following actions directly using the associated *Expression:* or *Digital Expression:* field:

- ◆ Blink.
- ◆ Close page.
- ◆ Colour Change (Analogue).
- ◆ Colour Change (Digital).
- ◆ Display Status Text.
- ◆ Display Text Point.
- ◆ Display Value.
- ◆ Edit point value (Analogue).
- ◆ Edit point value (Digital).
- ◆ Edit point value (Text).
- ◆ Enable/Disable.
- ◆ Horizontal move.
- ◆ Horizontal percentage fill.
- ◆ Resize height.
- ◆ Resize width.
- ◆ Rotate.
- ◆ Show page.
- ◆ Vertical move.
- ◆ Vertical percentage fill.
- ◆ Visible.

The following example of a simple expression contains a point ('redcars') attached to a particular object with an appropriate object action, Resize (Height). At runtime, once the value of the point has been met within the attributes declared within the *Active Expression Range/Required Height:* fields, the current object is resized accordingly. This example is an Integer or Real example, whereby the value of the point either falls inside or outside the specified range. In this example, the point 'redcars' must fall between 0 and 40 for the expression to be met.

Resize (Height)

Expression:
redcars

Active Expression Range / Required Height:

Minimum Value: 0 Minimum Height: 0
Maximum Value: 40 Maximum Height: 160

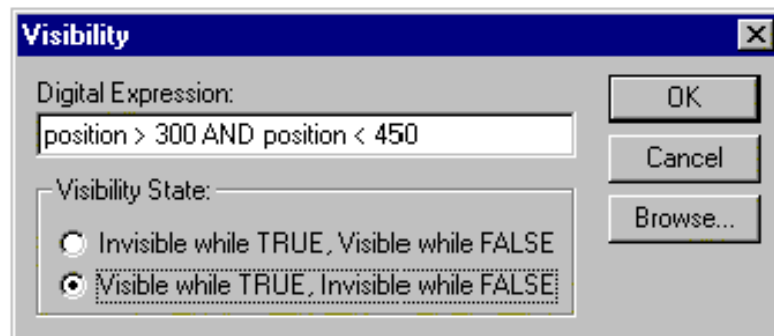

Justification:

Bottom Centre Top

OK
Cancel
Browse...

The following example of a more complex expression contains a test on point 'position'. If 'position' is more than 300 in value, and 'position' is less than 450 in value, i.e. the value of 'position' is between 300 and 450, then the expression has been met, and an action is initiated (in this instance the current object is made visible if the expression is met). This example is a Boolean example, whereby either the expression is met ('TRUE') or not met ('FALSE'). A Boolean value is always returned from a *Digital Expression*: field, as opposed to an *Expression*: field, which returns an Integer or Real value.

Operators used within this example are fully described in chapter 4, Logic and Arithmetic.

Visibility

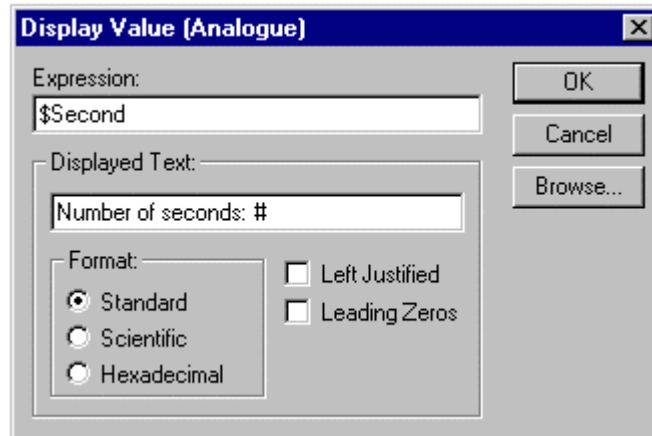

Digital Expression:
position > 300 AND position < 450

Visibility State:

Invisible while TRUE, Visible while FALSE
 Visible while TRUE, Invisible while FALSE

OK
Cancel
Browse...

The following example of an expression contains a value point 'prompt' which is included at the value position denoted by a '#' symbol.

Refer to the *CX-Supervisor User Manual* for detailed dialog descriptions.

CHAPTER 3

Scripts

A CX-Supervisor script is a simple programming language used to manipulate points. Scripts can be created at different levels, at object level, page level or project level. Although the script code can be applied to all levels of script, there are subtle differences, described in the following paragraphs.

Object

If a script is executed as a runtime action of an object, then the script can affect the object of the action, or any other, depending on the actual content of the script.

Page

Page scripts are concerned with manipulating points and graphical objects that are used or included within that page. In other words page scripts are used to drive a number of actions on the occurrence of a particular event. These actions may manipulate several graphical objects on one page.

Project

Scripts can be applied to a project to manipulate points. These scripts are associated with events that occur throughout the whole operating session

CHAPTER 4

Functions and Methods

This chapter describes the CX-Supervisor script language syntax. It provides a detailed definition of the syntax of CX-Supervisor scripts that drive project, page and object actions, and CX-Supervisor expressions as used by objects and scripts.

The following table describes the script language syntax at a glance.

Function Name	Function Type	Type	Remarks
&, , ^, <<, >>	bitwise operators	All	Applies bitwise expressions
(objects)	statement	OP	Specifies an object name for modification or test.
(points)	statement	All	Specifies a point name for modification or test.
+, -, *, /, %, =	arithmetic operators	All	Applies arithmetic expressions.
<, >, <=, >=, ==, !=	relational operators	All	Applies relational expressions.
AcknowledgeAlarm	alarm command	Scr	Acknowledges an alarm.
AcknowledgeAllAlarms	alarm command	Scr	Acknowledges all alarms.
AcknowledgeLatestAlarm	alarm command	Scr	Acknowledges the latest alarm.
Acos	unary function	All	Applies unary expression.
Asin	unary function	All	Applies unary expression.
Atan	unary function	All	Applies unary expression.
CancelForce	point command	Scr	Removes the forcing of values on a point.
Chr	text command	All	Displays a character based on the ASCII character set.
ClearAlarmHistory	alarm command	All	Clears the alarm history.
ClearErrorLog	event/error commands	All	Clears the error log.
ClearGraph	graph command	Scr	Clears the data from a trend or scatter graph.
ClearLogFile	Data Logging command	Scr	Clears a data log file
ClearSpoolQueue	printer command	All	Discards any queued messages or alarms.
close	object command	Scr	Closes a specified page.
CloseAlarmHistory	alarm command	All	Closes the current alarm history.
CloseAlarmStatus	alarm command	Scr	Closes the current alarm status.
CloseComponent	comms command	All	Closes a component for a PLC (e.g. CX-Server components).
CloseErrorLog	error command	Scr	Closes the currently open Error Log.
CloseFile	file command	Scr	Closes the open file.
CloseLogFile	Data Logging command	Scr	Closes a data log file
CloseLogView	Data Logging command	Scr	Closes the log viewer
ClosePLC	PLC command	Scr	Close communications with a PLC.
colour	object command	OP	Specifies a colour to an object.

Function Name	Function Type	Type	Remarks
CopyArray	point command	All	Copies the content of an array.
CopyFile	file command	Scr	Copies a specified file.
cos	unary function	All	Applies unary expression.
DDEEnable	DDE command	All	Enables DDE functions.
DDEExecute	DDE command	Scr	Sends a command to an app. via a DDE channel.
DDEInitiate	DDE command	Scr	Initiates a DDE conversation.
DDEOpenLinks	DDE command	Scr	Creates a DDE advise loop.
DDEPoke	DDE command	Scr	Uses open DDE channel to send information.
DDERequest	DDE command	Scr	Uses open DDE channel to request information.
DDETerminate	DDE command	Scr	Closes the specified DDE channel.
DDETerminateAll	DDE command	Scr	Closes all DDE channels.
DeleteFile	file command	Scr	Deletes the specified file.
disable	object command	OP	Disables an object.
DisableGroup	point command	All	Prevents a group of points to be read or written.
DisablePoint	point command	Scr	Disables communications to a point.
display	object command	Scr	Displays a specified page.
DisplayAlarmHistory	alarm command	Scr	Displays the current alarm history.
DisplayAlarmStatus	alarm command	Scr	Displays the alarm status of all current alarms.
DisplayErrorLog	event command	Scr	Displays the current Error Log.
DisplayRecipes	recipe command	Scr	View the current recipes in the project.
DownloadPLCProgram	PLC command	All	Downloads specified files to the PLC.
DownloadRecipe	recipe command	Scr	Downloads a specified recipe.
EditFile	file command	All	Edits a specified file.
EditGraph	graph command	Scr	Displays a dialog used for editing trend graphs.
EnableAlarms	alarm command	All	Enables alarm functions.
EnableDDE	comms command	Scr	Allows use of DDE functions.
EnableErrorLogging	error command	Scr	All actions become subject to Error Logging.
EnableGroup	point command	All	Permits a group of points to be read or written.
EnableOLE	comms command	Scr	Allows use of OLE functions.
EnablePLC	comms command	Scr	Allows use of PLC functions.
EnablePoint	point command	Scr	Enables communications to a point.
EnablePrinting	printer command	All	Permits printing of Alarms or messages.
ExportAndViewLog	Data Logging command	Scr	Exports data log and views
ExportLog	Data Logging command	Scr	Exports data log
FALSE	Boolean state	Scr	Applies Boolean expression.

Function Name	Function Type	Type	Remarks
FileExists	file command	All	Specifies the existence of a file.
Force	point command	Scr	Locks the value of a point.
ForceReset	point command	Scr	Sets a point value to 0.
ForceSet	point command	Scr	Sets a point value to 1.
FormatText	text command	All	Inserts text with standard 'C' formatting characters.
GenerateReport	report command	All	Produces a report based on a report template.
GetBit	point command	All	Retrieves a bit from a point.
GetPLCMode	PLC command	All	Retrieves the mode of a PLC.
GetPointValue	point command	Scr	Retrieves the value of a point.
GetSpoolCount	printer command	All	Specifies the number of alarms or messages queued for printing.
GetTextLength	text command	All	Specifies the number of characters in a text point.
height	object command	OP	Specifies the height of an object.
horizontal%fill	object command	OP	Specifies the horizontal fill of an object.
IFTHEN ELSE\ELSEIF ENDIF	statement	Scr	Applies a test to a script.
InputPoint	point command	Scr	Reads a value from a point.
IsAlarmAcknowledged	alarm command	Scr	Tests if a specified alarm has been acknowledged.
IsAlarmActive	alarm command	Scr	Tests if a specified alarm is currently active.
Left	statement	Scr	Extracts characters from the left of a string
log	unary function	All	Calculates the natural logarithm on a number.
log10	unary function	All	Calculates the base-10 logarithm on a number.
LogError	error command	Scr	Logs an error message with the error logger.
LogEvent	error command	Scr	Logs an event message with the error logger.
Login	security command	Scr	Logs a user into a run-time application.
Logout	security command	Scr	Logs a user out of a run-time application.
Message	text command	Scr	Outputs a string in a message box.
Mid	text command	Scr	Extracts a substring from a string.
move	object command	OP	Moves an object.
MoveFile	file command	Scr	Moves the specified file.
OpenComponent	comms command	All	Opens a component for a PLC (e.g. CX-Server components).
OpenFile	file command	Scr	Opens the specified file.

Function Name	Function Type	Type	Remarks
OpenLogFile	Data Logging command	Scr	Opens a data log file
OpenLogView	Data Logging command	Scr	Opens the Data Log Viewer
OpenPLC	PLC command	Scr	Opens communications with a PLC.
OR, AND, NOT	logical operators	All	Applies logical expressions.
OutputPoint	point command	Scr	Displays the current value of a point.
PlayOLE	gen. command	Scr	Plays an OLE object.
PlaySound	gen. command	Scr	Plays a sound file.
PLCCommsFailed	PLC command	All	Specifies if the PLC communications have failed.
PLCMonitor	PLC command	Scr	Monitors a PLC.
PointExists	point command	All	Specifies the existence of a point.
PrintActivePage	gen. command	Scr	Prints the currently active page.
PrintFile	file command	Scr	Prints the specified file.
PrintMessage	text command	All	Prints messages to the configured 'Alarm/message printer'.
PrintPage	gen. command	Scr	Prints the specified page.
PrintReport	report command	All	Prints a report
PrintScreen	gen. command	Scr	Prints the current display screen.
PrintSpoolQueue	printer command	All	Prints all queued alarms or messages.
Rand	gen. command	Scr	Calculates a random number.
Read	file command	Scr	Reads data from an open file into a point.
ReadMessage	file command	All	Reads text from an external file.
REM	statement	Scr	Remarks on line or lines of script.
RETURN	statement	Scr	Stops sequential execution of script.
Right	text command	Scr	Extracts characters from the right of a string.
rotate	object command	OP	Rotates an object.
RunApplication	gen. command	Scr	Runs the specified application.
RunHelp	gen. command	Scr	Runs the specified help file.
SaveGraph	graph command	All	Saves graph data to disk.
SELECT CASE/END SELECT	statement	Scr	Applied to complex tests.
SelectFile	file command	All	Specifies a file name and path.
SetBit	point command	All	Sets a specific bit from a point.
SetPLCMode	PLC command	All	Sets the mode of a PLC.
SetPLCPhoneNumber	PLC command	All	Sets a phone number to a PLC.
SetPointValue	point command	Scr	Sets the value of a point.
SetPrinterConfig	printer command	All	Defines printer configuration.
SetupUsers	security command	Scr	Defines users and passwords for Login.
ShutDown	gen. command	Scr	Terminates CX-Supervisor.
sin	unary function	All	Applies unary expression.

Function Name	Function Type	Type	Remarks
Snapshot	graph command	Scr	Stores the current state of a trend graph.
sqrt	unary function	All	Applies unary expression.
StartGraph	graph command	Scr	Starts the recording of a graphs data.
StartLogging	Data Logging command	Scr	Starts a data set logging.
StopGraph	graph command	Scr	Stops the recording of a graphs data.
StopLogging	Data Logging command	Scr	Stops a data set logging.
tan	unary function	All	Applies unary expression.
TCAutoTune	temp. controller command	All	Starts or stops a temperature controller auto-tune operation.
TCBackupMode	temp. controller command	All	Defines how a temperature controller stores internal variables.
TCGetStatusParameter	temp. controller command	All	Retrieves the temperature controller status parameter.
TCRemoteLocal	temp. controller command	All	Defines the operational mode of a temperature controller.
TCRequestStatus	temp. controller command	All	Retrieves the temperature controller status.
TCReset	temp. controller command	All	Resets the temperature controller.
TCRspLsp	temp. controller command	All	Defines the setpoint mode used by the temperature controller.
TCRunStop	temp. controller command	All	Defines either auto-output mode shift or manual output mode shift.
TCSaveData	temp. controller command	All	Saves data associated with the temperature controller.
TCSettingLevel1	temp. controller command	All	Performs a settinglevel function for the temperature controller.
TextToValue	text command	Scr	Converts a string to a numerical point value.
TRUE	Boolean state	Scr	Applies Boolean expression.
UploadPLCProgram	PLC command	All	Uploads programs in the PLC to specified files.
ValueToText	text command	Scr	Converts a numerical value into a text point.
vertical%fill	object command	OP	Specifies the vertical fill of an object.
ViewReport	report command	All	Displays a report
visible	object command	OP	Toggles the visibility of an object.
width	object command	OP	Specifies the width of an object.
Write	file command	Scr	Writes a value to an open file.
WriteMessage	file command	All	Writes text to an external file.

The 'Type' column refers to the types of script and expression the function can be applied to. 'All' refers to both expressions and scripts. 'Scr' refers to scripts only. 'OP' refers to Object and Page scripts only.

The style of this annex is such that each element of the script language is described in turn, describing scope, syntax with remarks, typical examples and references. References are always forward; for instance, if an example contains elements not yet described, a suitable reference is included; however if an example contains elements already described, no reference is made.

Points

Basic Point Assignment

Syntax

```
pointname = expression
```

Remarks

Argument	Description
<i>pointname</i>	The point name to be assigned a value.
<i>expression</i>	The value to be assigned to <i>pointname</i> . The expression may be of type Boolean, Integer, Real or Text.

Typical Examples

```
count = 100
```

The Integer or Real point 'count' is assigned the value 100.

```
result = TRUE
```

The Boolean point 'result' is assigned the state "TRUE".

```
name = "Valve position"
```

The Text point 'name' is assigned the associated text, contained within quotation marks.

References

Refer to chapter 4, Punctuation for details of the use of quotation marks.

Further Point Assignment

Syntax

```
pointname = expression
```

Remarks

Argument	Description
<i>pointname</i>	The point name to be assigned a value.
<i>expression</i>	The value to be assigned to <i>pointname</i> . The expression may be of type Boolean, Integer or Real and can include other points, logical or arithmetical expressions. Mathematical precedence is applied as follows: <ul style="list-style-type: none"> • Parenthesis (highest). • Unary minus and NOT logical operator. • Multiplication, division and modulus. • Addition and subtraction. • Greater than, less than, greater than or equal to, and less than or equal to relational operators. • Shift Left (SHL) and Shift Right (SHR). • Equal to and not equal to relational operators. • Bitwise AND, XOR, OR. • AND logical operator, OR logical operator (lowest).

Typical Examples

```
lift = height + rate/5.0
```

The Integer or Real point 'lift' is assigned the value calculated by the value of point 'rate' divided by 5, plus the value of point 'height'. Precedence can be changed by the introduction of parenthesis.

```
lift = lift - 0.2
```

The Integer or Real point 'lift' is assigned the value calculated by the current value of point 'lift' minus 0.2.

```
distance = distance * time
```

The Integer or Real point 'distance' is assigned the value calculated by the current value of point 'distance' multiplied by point 'time'.

References

Refer to chapter 4, Logic and Arithmetic for details of the use of arithmetic and logic functions. Refer to chapter 4, Punctuation for details of the use of parenthesis.

Logic and Arithmetic

Arithmetic Operators

Syntax

```
pointname = expression
```

Remarks

Argument	Description
<i>pointname</i>	The point name to be assigned a value based on an arithmetical expression.
<i>expression</i>	The value to be assigned to <i>pointname</i> . The expression may include the following operators with points and constants: <ul style="list-style-type: none"> • Addition '+'. • Subtraction '-'. • Multiplication '*'. • Division '/'. • Modulus '%'.

Typical Examples

```
result = 60 + 20/5
```

The Integer or Real point 'result' is assigned the value calculated by the value of 20 divided by 5, plus 60.

```
lift = height + rate/5.0
```

The Integer or Real point 'lift' is assigned the value calculated by the value of point 'rate' divided by 5, plus the value of point 'height'. Precedence can be changed by the introduction of parenthesis.

References

Refer to chapter 4, Punctuation for details of the use of parenthesis.

Bitwise Operators

Syntax

```
pointname = expression
```

or

```
IF expression
```

or

```
DO WHILE expression
```

or

```
DO UNTIL expression
```

Remarks

Argument	Description
<i>pointname</i>	The pointname to be assigned a value based on the bitwise operation.
<i>expression</i>	The value to be assigned to <i>pointname</i> , or to be evaluated as a Boolean expression. The expression can include the following operators with points and constants: <ul style="list-style-type: none"> • Bitwise AND, 'BITAND' or '&'. • Bitwise OR, 'BITOR' or ' '. • Bitwise XOR, 'XOR' or '^'. • Bitwise Shift Left, 'SHL' or '<<'. • Bitwise Shift Right, 'SHR' or '>>'.

Typical Examples

```
MSB = value & 128
```

The Boolean point 'MSB' is set 'TRUE' if the binary representation of 'value' has the bit set which is worth 128.

```
Pattern = value << 2
```

The binary representation of 'value' is shifted left twice, and stored in 'pattern'. Each Shift Left operation has the effect of doubling the value, so two shifts quadruple the value.

Logical Operators**Syntax**

```
pointname = expression
```

or

```
IF expression
```

or

```
DO WHILE expression
```

or

```
DO UNTIL expression
```

Remarks

Argument	Description
<i>Pointname</i>	The point name to be assigned a value based on a logical expression.
<i>Expression</i>	The Boolean value to be assigned to <i>pointname</i> or the Boolean value forming a conditional statement. The expression includes the following operators with points and constants: <ul style="list-style-type: none"> • And 'AND'. • Or 'OR'. • Not 'NOT'.

Typical Examples

```
flag = temp AND speed
```

The Boolean point 'flag' is assigned a value based on the logic of point 'temp' AND point 'speed'. If 'temp' and 'speed' are both not zero, 'flag' is set to 1, or "TRUE". A value of zero in either 'temp' or 'speed' supplies 'FALSE' or 0 to 'flag'.

```
IF flag AND temp AND speed THEN
  flag = FALSE
ENDIF
```

The Boolean point 'flag' is assigned 'FALSE', on the condition that 'flag' AND point 'temp' AND point 'speed' are all not zero. If the condition fails, then 'flag' is not assigned 'FALSE'.

References

Refer to chapter 4, Control Statements for details of the use of the IF THEN ELSE/ELSEIF ENDIF statements.

Relational Operators**Syntax**

```
IF expression
or
DO WHILE expression
or
DO UNTIL expression
```

Remarks

Argument	Description
<i>Expression</i>	<p>The value forming a conditional statement. The expression may include the following operators with points and constants:</p> <ul style="list-style-type: none"> • Greater than '>'. • Less than '<'. • Greater than or equal to '>='. • Less than or equal to '<='. • Not equal to '!='. • Equal to '=='.

Typical Example

```
IF fuel < 0 THEN
  fuel = 0
ENDIF
```

The point 'fuel' is assigned the value 0 on the condition that currently, 'fuel' is less than 0. If 'fuel' is not less than 0, then it is not assigned the new value.

References

Refer to chapter 4, Control Statements for details of the use of the IF THEN ELSE/ELSEIF ENDIF statements.

Control Statements**Simple Conditional Statements****Syntax**

```
IF condition THEN
  statementblock1
ENDIF
```

or

```
IF condition THEN
  statementblock1
ELSE
  statementblock2
ENDIF
```

Remarks

Argument	Description
<i>Condition</i>	The condition is made up of points and constants, using relational, logical or arithmetical notation as a test. The condition can evaluate Boolean state 'TRUE' and 'FALSE', Integer or Real numbers, or a text string.
<i>Statementblock1</i>	One or more statements which are performed if the <i>condition</i> is met.
<i>Statementblock2</i>	One or more statements which are performed if the <i>condition</i> is not met.

Typical Examples

```
IF fuel < 0 THEN
  fuel = 0
ENDIF
```

Provided Integer point 'fuel' is less than 0, then it is assigned the value 0.

```
IF burner THEN
  fuel = fuel - rate
ENDIF
```

Provided Boolean point 'burner' is "TRUE", then Integer point 'fuel' is assigned a new value. It is also possible to apply 'IF burner == TRUE THEN' as the first line, with identical results.

```
IF distance > 630 AND distance < 660 AND lift >= -3 THEN
  winner = TRUE
  burner = FALSE
ENDIF
```

Provided that Integer point 'distance' is greater in value than 630 AND 'distance' is less in value than 660 (i.e. 'distance' is a value between 630 and 660) AND point 'lift' is greater than or equal to -3, then Boolean points 'winner' and 'burner' are assigned new values.

```
IF burner AND fuel > 0 AND rate > 0 THEN
  fuel = fuel - rate
ELSE
  lift = 0
  altitude = 0
ENDIF
```

Provided that Boolean point 'burner' is "TRUE" AND points 'fuel' and 'rate' are greater in value than 0, then 'fuel' is assigned a new value. Otherwise points 'lift' and 'altitude' are assigned a new value.

References

Refer to chapter 2, Indentation for details on the layout of code.

Nested Conditional Statements

Syntax

```
IF conditionA THEN
  statementblock1
  IF conditionB THEN
    statementblock3
  ENDIF
ELSE
  statementblock2
ENDIF
```

or

```
IF conditionA THEN
  statementblock1
  IF conditionB THEN
    statementblock3
  ELSE
    statementblock4
  ENDIF
ELSE
  statementblock2
ENDIF
```

or

```

IF conditionA THEN
  statementblock1
ELSEIF conditionB THEN
  statementblock3
ENDIF

```

or

```

IF conditionA THEN
  statementblock1
ELSE
  statementblock2
  IF conditionB THEN
    statementblock3
  ELSE
    statementblock4
  ENDIF
ENDIF

```

Remarks

Argument	Description
<i>conditionA</i>	The condition is made up of points and constants, using relational, logical or arithmetical notation as a test. The condition can evaluate Boolean state 'TRUE' and 'FALSE', Integer or Real numbers, or a text string.
<i>conditionB</i>	This condition is nested in the first condition, either on a successful or unsuccessful evaluation of <i>conditionA</i> . The condition is made up of points and constants, using relational, logical or arithmetical notation as a test. The condition can evaluate Boolean state 'TRUE' and 'FALSE', Integer or Real numbers, or a text string. There is no limit to the number of nested conditional statements.
<i>statementblock1</i>	One or more statements which are performed if <i>conditionA</i> is met.
<i>statementblock2</i>	One or more statements which are performed if <i>conditionA</i> is not met.
<i>statementblock3</i>	One or more statements which are performed if <i>conditionB</i> is met.
<i>statementblock4</i>	One or more statements which are performed if <i>conditionB</i> is not met.

Typical Examples

```

IF burner AND fuel > 0 AND rate > 0 THEN
  lift = lift + rate/5
ELSE
  count = 1
  IF altitude > 140 THEN
    lift = lift - 0.2
  ENDIF
ENDIF

```

Provided a successful evaluation has been made to points 'burner' AND 'fuel' AND 'rate', point 'lift' is updated with the current value of rate divided by 5 plus 'lift'. Otherwise, a further evaluation is required on point 'altitude'. If 'altitude' is currently greater than 140, then 'lift' is decremented by 0.2.

```
IF burner AND fuel > 0 AND rate > 0 THEN
    lift = lift + rate/5
ELSE
    IF altitude > 140 THEN
        lift = lift - 0.2
    ENDIF
ENDIF

IF burner AND fuel > 0 AND rate > 0 THEN
    lift = lift + rate/5
ELSEIF altitude > 140 THEN
    lift = lift - 0.2
ENDIF
```

These two examples are identical. The use of the ELSEIF statement combines the ELSE statement and the IF/ENDIF statements for brevity. It is acceptable to have more than one ELSEIF statement in an IF THEN ELSE/ELSEIF ENDIF construct.

References

Refer to chapter 4, Punctuation for details of the use of indentation.

Case Select

Syntax

```
SELECT CASE expression
    CASE expression
        statementblock1
    CASE expression
        statementblock2
    CASE expression
        statementblock3
END SELECT
```

or

```
SELECT CASE expression
    CASE expression
        statementblock1
    CASE expression
        statementblock2
    CASE ELSE
        statementblock3
END SELECT
```

Remarks

Argument	Description
<i>expression</i>	The <i>expression</i> may be a point, or a calculation of constants and/or points that produces a result.
<i>statementblock1</i>	One or more statements that are only performed if the preceding CASE expression is met.
<i>statementblock2</i>	One or more statements that are only performed if the preceding CASE expression is met.
<i>statementblock3</i>	One or more statements that are only performed if the preceding CASE expression is met.

Typical Examples

```

SELECT CASE colourvalue
  CASE 1
    colour (blue)
  CASE 2
    colour (green)
  CASE 3
    colour (cyan)
  CASE ELSE
    colour (0)
END SELECT

```

This example shows the assignment of a colour according to the value of a point. The value of Integer point 'colourvalue' is evaluated and compared with each case until a match is found. When a match is found, the sequence of actions associated with the CASE statement is performed. When 'colourvalue' is 1, the colour given to the current object is blue, when 'colourvalue' is 2, the colour given to the current object is green, when 'colourvalue' is 3, the colour given to the current object is cyan. If 'colourvalue' falls outside the integer range 1—3, then the colour given is 0 (black). Like ELSE and ELSEIF, the CASE ELSE statement is optional.

```

SELECT CASE TRUE
  CASE temperature > 0 AND temperature <= 10
    colour (blue)
  CASE temperature > 10 AND temperature <= 20
    colour (green)
  CASE temperature > 20 AND temperature <= 30
    colour (red)
  CASE ELSE
    colour (white)
ENDSELECT

```

In this example, instead of using a point as the condition as with the previous example, the value is the condition — in this case Boolean state "TRUE" — with the integer point 'temperature' being tested at each case. If it is "TRUE" that 'temperature' is between 0 and 10, then the current object is set to blue, or if it is "TRUE" that 'temperature' is between 11 and 20, then the current object is set to green, or if it is "TRUE" that 'temperature' is between 21 and 30, then the current object is set to red. If none

of these CASE statements are met, then the current object is set to white. Like ELSE and ELSEIF, the CASE ELSE statement is optional.

References

Refer to chapter 4, Object Commands for details of applying attributes to an object and for the use of the Colour object command. Refer to chapter 6, Colour Palette for details of the Colour Palette colour designation.

FOR... NEXT Loop

Syntax

```
FOR pointname = startpt TO endpt STEP steppt
  statementblock1
NEXT
```

Remarks

Argument	Description
<i>pointname</i>	The pointname to be used as the loop counter.
<i>startpt</i>	The initial setting of <i>pointname</i> , and the first value to be used through the loop.
<i>endpt</i>	The last value to be used. The loop ends when <i>pointname</i> exceeds this value.
<i>steppt</i>	Amount to increase <i>pointname</i> by every pass of the loop. <i>Steppt</i> can be negative to count backwards providing <i>startpt</i> is larger than <i>endpt</i> . The STEP keyword and variable may be omitted in which case <i>pointname</i> is incremented at each pass of the loop (identical to adding STEP 1).

Typical Examples

```
FOR loopcount = 0 TO 100
  Ellipse_1.vertical%fill = loopcount
NEXT
```

In this example, 'Ellipse_1' is gradually filled 100 times.

```
FOR loopcount = 100 TO 0 STEP -5
  Ellipse_1.vertical%fill = loopcount
NEXT
```

In this example, the fill for 'Ellipse_1' is gradually removed 20 times (100 times/-5).

Note: Loop statements should be used with caution, as they consume processor time while they are running and some other parts of the system may not be updated.

DO WHILE/UNTIL Loop

Syntax

```
DO WHILE expression
  statementblock
LOOP
```

or

```
DO
  statementblock
LOOP WHILE expression
```

or

```
DO UNTIL expression
  statementblock
LOOP
```

or

```
DO
  statementblock
LOOP UNTIL expression
```

Remarks

Argument	Description
<i>expression</i>	The <i>expression</i> may be a point, or a calculation of constants and/or points that produces a result.
<i>statementblock</i>	One or more statements to be executed multiple times depending on expression.

Typical Example

```
DO WHILE dooropen == TRUE
  Message ("You must shut the door before continuing")
LOOP
DO
  nextchar = Mid (Mystring, position, 1)
  position = position + 1
LOOP UNTIL nextchar = "A"
```

Note: Loop statements should be used with caution, as they consume processor time while they are running and some other parts of the system may not be updated.

Subroutines

Call

Syntax

```
CALL subroutine (arguments)
```

Remarks

Argument	Description
<i>subroutine</i>	The name of the subroutine defined at project level.
<i>arguments</i>	The list of arguments required by the <i>subroutine</i> separated by commas. Each argument may be a pointname, constant, arithmetical or logical expression or any valid combination.

Typical Example

```
CALL MySub ($Second, "Default", 2 + Int1)
```

Return

Syntax

```
RETURN
```

Typical Example

```
IF limit > 1000 THEN
  RETURN
ELSE
  value = limit
ENDIF

REM final part of script
POLYGON_1.COLOUR = red
ELLIPSE_5.WIDTH = value
```

The integer point 'limit' is tested for its value. If its value exceeds 1000, then the condition is met, and the RETURN command is executed. All statements after the RETURN command are ignored. If the value of integer point 'limit' does not exceed 1000, then the RETURN command is not executed, and statements after the RETURN command are performed.

References

Refer to the *CX-Supervisor User Manual* for the use of the RETURN statement for Recipe validation.

Object Commands

Current Object

Syntax

```
objectcommand
```

Remarks

Argument	Description
<i>objectcommand</i>	<ul style="list-style-type: none"> • The expression can be made up of the following commands, which are also described <i>in</i> chapter 4, Object Commands: • Colour command. • Disable command. • Visible command. • Move command. • Rotate command. • Vertical fill command. • Horizontal fill command. • Height command. • Width command. <p>The content of the commands are made up of arithmetical or logical expressions, x and y co-ordinates, or references, varying between commands. The colour command requires a colour identifier.</p>

Typical Example

```
colour (red)
```

The current object is specified as red in colour.

References

Other Objects

Syntax

```
objectname.objectcommand
```

```
pagename.objectname.objectcommand
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. The object is provided with a generic name on creation, which can be amended later to something more meaningful. The script is automatically updated following any amendment to the object name.
<i>objectcommand</i>	This can be made up of the following commands, which are described in chapter 4, Object Commands: <ul style="list-style-type: none"> • Blink command • Colour command. • Disable command. • Visible command. • Move command. • Rotate command. • Vertical fill command. • Horizontal fill command. • Height command. • Width command. <p>The content of the commands are made up arithmetical or logical expressions, x and y co-ordinates, or references, varying between commands. The colour command requires a colour identifier.</p>

Typical Examples

```
POLYGON_1.colour (red)
```

```
POLYGON_1.colour = red
```

The specified object, 'POLYGON_1' is set to be red in colour.

References

Refer to:

- ◆ *CX-Supervisor User Manual* for details of object names.

- ◆ Chapter 4, Height for use of the height command.
- ◆ Chapter 4, Horizontal Fill for use of the horizontal fill command.
- ◆ Chapter 4, Move for use of the move command.
- ◆ Chapter 4, Rotate for use of the rotate command.
- ◆ Chapter 4, Vertical Fill for use of the vertical fill command.
- ◆ Chapter 4, Visible for use of the visible command.
- ◆ Chapter 4, Width for use of the width command.

Blink

Syntax

```
objectname.blink (colour, status)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>colour</i>	Colour to blink to. Some colour values within the colour palette have a meaningful <i>colourID</i> . This takes the form of the colour name, e.g., 'black' or 'yellow'. Alternatively, an integer value of 0x1000000 can be added to a number 0-65 to select a palette entry.
<i>status</i>	This argument may be omitted. May be on of: TRUE – turn blinking On. FALSE – turn blinking Off. If omitted, TRUE is assumed.

Typical Examples

```
blink (red, TRUE)
```

Start blinking red.

```
LINE_1.blink(0xFFFF00, status)
```

The object LINE_1 starts or stops blinking yellow depending on value of Boolean point 'status'.

Colour

Syntax

```
objectname.colour (expression, context)
colour (expression, context)
```

or

```
objectname.colour (colourID, context)
colour (colourID, context)
```

An equals sign may be used as an alternative to brackets:

```
objectname.colour = expression
colour = expression
```

or

```
objectname.colour = colourID
colour = expression
```

Either spelling 'colour' or 'color' is acceptable.

Note: An equals sign may also be used for most other object commands, even if it is not directly specified in this manual.

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	The <i>expression</i> may be an Integer point, or a calculation of constants and/or points that produce an Integer value between 0 and 16777215. This is the desired colour's RGB value. (format is 0xBBGGRR).
<i>colourID</i>	Some colour values within the colour palette have a meaningful <i>colourID</i> . This takes the form of the colour name, e.g., 'black' or 'yellow'. Alternatively, an integer value of 0x1000000 can be added to a number 0-65 to select a palette entry.
<i>context</i>	This argument is optional and may be omitted. It defines which part of the object has its colour changed. May be one or more of: @FILL – change fill colour @FRAME – changes frame colour If omitted both are changed. Equivalent to @FILL @FRAME

Typical Examples

```
TEXT_3.colour (blue)
```

or

```
TEXT_3.colour = blue
```

The object 'TEXT_3' is set to blue.

```
BALL.color (35 + 0x1000000)
```

The object 'BALL' is set to colour 35 from the colour palette.

```
BALL.colour (0xFF0000,@FILL)
```

The object 'BALL' is set to blue.

```

shade = tint1 + tint2
IF shade > 65 OR shade < 0 THEN
  shade = 0
ENDIF
ELLIPSE_1.colour (shade + 0x1000000)

```

The point 'shade' is set to a value based on 'tint1' and 'tint2', and is tested first to ensure that it is a value between 0 and 65. If 'shade' falls outside this range, then it cannot be applied as a colour to an object, and is therefore reset to 0 (or black). ELLIPSE_1' is set to the palette colour of the value of shade.

References

Refer to chapter 6, Colour Palette for details of colour names and colour numbers.

Disable

Syntax

```
objectname.disable (expression)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the selectable object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	The expression can be made up of points resulting in 'TRUE' or 'FALSE'.

Typical Examples

```
disable (TRUE)
```

The current pushbutton object to which this example applies is disabled.

```
PUSH_8.disable (count AND flag)
```

The selectable object 'PUSH_8' is disabled provided Integer point 'count' AND Boolean point 'flag' return "TRUE".

Height

Syntax

```
objectname.height (expression, context)
```

```
objectname.height = expression
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object, following any amendment to the object name. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	This is a value, point or an arithmetic expression returning a new height value in pixels.
<i>context</i>	This argument is optional and may be omitted. It defines which part of the object is the datum, and remains static. May be one of: @TOP – uses object top as datum. @CENTRE – uses object centre as datum @BOTTOM – uses object bottom as datum If omitted @CENTRE is assumed

Typical Examples

```
height (100)
or
height = 100
```

The height of the current object is set to 100.

```
LINE_1.height (stretch/offset, @top)
```

The height of object 'LINE_1' is changed to the value calculated by points 'stretch' and 'offset', keeping the top where it is.

Horizontal Fill**Syntax**

```
objectname.horizontal%fill (expression, context)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	This is an arithmetic expression that must return a value between 0 and 100. On return of a valid result, the fill commences from left to right.
<i>context</i>	This argument is optional and may be omitted. It defines which side of the object is filled from. May be one of: @LEFT – fill from the left @RIGHT – fill from the right If omitted, @LEFT is assumed

Typical Examples

```
horizontal%fill (50)
```

The current object to which this example applies is filled by 50%.

```
ELLIPSE_1.horizontal%fill (GAS_LEVEL, @RIGHT)
```

The object 'ELLIPSE_1' is filled from the right, provided the point 'GAS_LEVEL' returns a valid result, between 0 and 100.

Move**Syntax**

```
objectname.move (x co-ordinate, y co-ordinate)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. following any amendment to the object name. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>x co-ordinate</i> <i>y co-ordinate</i>	The <i>x</i> and <i>y</i> co-ordinates of the origin of the object at its resultant position in pixels are specified in the form (<i>x</i> , <i>y</i>). Points alone or as part of an arithmetic expression may be used as a basis for this expression.

Typical Examples

```
move (100, 200)
```

The current object to which this example applies is moved to the specified position.

```
POLYGON_1.move (xpos, ypos/5)
```

The object 'POLYGON_1' is moved to the position specified by points 'xpos' and 'ypos' divided by 5.

Rotate**Syntax**

```
objectname.rotate (angle, context, fixed, xcoord, ycoord)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>angle</i>	The angle of rotation can range between 0 to 360 in a clockwise direction. Points alone, or as part of an arithmetic expression may be used as an angle.
<i>context</i>	This argument is not required and may be omitted. May be one of: @TOPLEFT – rotate around top left of object @TOPCENTRE – rotate around top centre of object @TOPRIGHT – rotate around top right of object @CENTRELEFT – rotate around centre left of object @CENTRE – rotate around centre of object @CENTRERIGHT – rotate around centre right of object @BOTTOMLEFT – rotate around bottom left of object @BOTTEMCENTRE – rotate around bottom centre of object @ BOTTOMRIGHT – rotate around bottom right of object @USERDEFINED – user defined point specified in <i>xcoord</i> and <i>ycoord</i> .
<i>fixed</i>	This argument may be omitted. If this boolean value is true, the rotation origin is fixed to the screen, even if the object is moved. Otherwise, the rotation origin is relative to object position.
<i>xcoord</i> <i>ycoord</i>	Only required if @USERDEFINED is specified. These integer variables specify the rotation origin in pixels

Typical Examples

```
rotate (45)
```

The current object to which this example applies is rotated by 45°.

```
ELLIPSE_1.rotate(tilt, @USERDEFINED, 0, -100, 10)
```

The object 'ELLIPSE_1' is rotated by the value of 'tilt', about a point -100, 10 relative to the objects current position.

```
rotate (a * sin(b))
```

The current object is rotated based on the result of an arithmetic expression involving points named 'a' and 'b'.

Vertical Fill

Syntax

```
objectname.vertical%fill (expression, context)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	This is an arithmetic expression that must return a value between 0 and 100. On return of a valid result, the fill commences from bottom to top.
<i>context</i>	This argument may be omitted. May be one of: @DOWN – Fill object downwards @UP – Fill object upwards If omitted, @UP is assumed

Typical Examples

```
vertical%fill (50)
```

The current object to which this example applies is filled by 50%.

```
ELLIPSE_1.vertical%fill (OIL_QUANTITY, @DOWN)
```

The object 'ELLIPSE_1' is filled provided the point 'OIL QUANTITY' returns a valid result, between 0 and 100.

Visible**Syntax**

```
objectname.visible (expression)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	The expression can be made up of points resulting in 'TRUE' or 'FALSE'.

Typical Examples

```
visible (TRUE)
```

The current object to which this example applies becomes visible.

```
POLYLINE_8.visible (count AND flag)
```

The object 'POLYLINE_8' is made visible provided Integer point 'count' AND Boolean point 'flag' return "TRUE".

Width

Syntax

```
objectname.width (expression, context)
```

Remarks

Argument	Description
<i>objectname</i>	This is the name of the object. Where a script is directly attached to an object, <i>objectname</i> is not required.
<i>expression</i>	This is a value, point or an arithmetic expression returning a new width value in pixels.
<i>context</i>	This argument may be omitted. May be one of: @LEFT – use left of object as datum. @CENTRE – use centre of object as datum. @RIGHT – use right of object as datum. If omitted, @CENTRE is assumed.

Typical Examples

```
width (150)
```

The width of the current object is set to 150.

```
LINE_1.width (squeeze/offset, @RIGHT)
```

The width of object 'LINE_1' is changed to the value calculated by points 'squeeze' and 'offset', keeping the rightmost point fixed.

Page Commands

Display Page

Syntax

```
display ("pagename")
```

Remarks

Argument	Description
<i>pagename</i>	This is the name of the page for display, based on its filename without the file extension, e.g. the <i>pagename</i> for CAR.PAG is simply 'CAR'.

Typical Examples

```
display ("CAR")
```

The page 'CAR.PAG' is displayed.

```
textpoint = "CAR"
display(textpoint)
```

The page 'CAR.PAG' is displayed.

Close Page**Syntax**

```
close ("pagename")
```

Remarks

Argument	Description
<i>pagename</i>	This is the name of the page for closure, based on its filename without the file extension, e.g. the <i>pagename</i> for CAR.PAG is simply 'CAR'. The <i>pagename</i> for closure must be currently open.

Typical Examples

```
close("CAR")
```

The page 'CAR.PAG' is closed.

```
textpoint = "CAR"
close(textpoint)
```

The page 'CAR.PAG' is closed.

General Commands**Exponential****Syntax**

```
result = Exp (value, exponent)
```

Remarks

Argument	Description
<i>result</i>	Point name to receive returned result of <i>value</i> raised to the power of <i>exponent</i> .
<i>value</i>	Number to raise.
<i>exponent</i>	Power to raise <i>value</i> by.

Typical Example

```
MSBMask = Exp (2, 15)
```

In this example, 'MSBMask' is assigned the value 2^{15} , i.e. 32,768.

PlayOLE**Syntax**

```
returnstate = PlayOLE("objectname",OLEVerbNumber)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>objectname</i>	string	The identifier of the OLE object to be played.
<i>OLEVerbNumber</i>	integer	The verb number has a specific meaning to the OLE application. Typical values are: 0: specifies the action that occurs when an end-user double clicks the object in its container. The object determines this action (often 'edit' or 'play'). -1: instructs the object to show itself for editing or viewing. Usually an alias for some other object-defined verb. -2: instructs an object to open itself for editing in a window separate from that of its container. -3: causes an object to remove its user interface from the view. Applies only to objects that are activated in-place. Positive numbers designate object specific verbs.

Typical Example

```
PlayOLE("ole_1",0)
```

The object 'ole_1' is played using its primary verb.

PlaySound**Syntax**

```
returnstate = PlaySound("soundfile")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>soundfile</i>	string	Path of sound file to be played.

Typical Example

```
PlaySound("c:\noise.wav")
```

The soundfile "c:\noise.wav" is played.

Rand**Syntax**

```
pointname = Rand(upperlimit)
```

Remarks

Argument	Type	Description
<i>upperlimit</i>	integer	The maximum negative or positive integer value that the Rand function can generate.
<i>pointname</i>	Integer point	Point that contains the integer returned from the Rand function.

Typical Example

```
randomnumber = Rand(upperlimit)
```

A random integer in the range 0 to upperlimit is returned and contained in the point 'randomnumber'. Maximum upperlimit is 32767.

Note: If 'upperlimit' is negative then the range is 0 to the negative number.

RunApplication**Syntax**

```
returnstate = RunApplication("executable")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>executable</i>	string	Pathname of executable file.

Typical Example

```
RunApplication("c:\myprog.exe")
```

The executable file c:\myprog.exe is run.

RunHelp

Syntax

```
returnstate = RunHelp("helpfile",helpindex)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>helpfile</i>	string	Pathname of helpfile to be run.
<i>helpindex</i>	integer	Index into a help topic as defined by the help file being run.

Typical Example

```
RunHelp("c:\myhelp.hlp",0)
```

The helpfile c:\myhelp.hlp is run, and topic 0 shown.

ShutDown

Syntax

```
returnstate = ShutDown()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
ShutDown()
```

CX-Supervisor runtime operation is terminated.

Sleep

Syntax

```
Sleep (duration)
```

Remarks

Argument	Type	Description
<i>Duration</i>	- - -	Number of milliseconds to wait before continuing.

Typical Example

```
Sleep (1000)
```

CX-Supervisor waits 1 second.

Note: The sleep statement should be used with caution, as some other parts of the system may not be updated while a script is sleeping.

Communications Commands

CloseComponent

Syntax

```
Returnstate = CloseComponent(ComponentName, PLCName)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>ComponentName</i>	text	A Text point or text constant containing the name of the component to close.
<i>PLCName</i>	text	Text point or text constant containing the name of the PLC that the component to close is attached to.

Typical Examples

```
CloseComponent("PLC Data Monitor", "MyPLC")
```

In this example, the PLC Data Monitor component monitoring the PLC 'MyPLC' is closed.

```
Component = "Performance Monitor"
PLC = "PLC06"
OK = CloseComponent(Component, PLC)
```

In this example, the Performance Monitor component monitoring the PLC 'PLC06' is closed. 'OK' is used to determine if the action was successful.

EnabledDE

Syntax

```
returnstate = EnabledDE(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Pointname</i>	bool point	A Boolean point that holds the required enable/disable state

Typical Examples

```
EnableDDE(result)
```

DDE functions are enabled based on the value of point 'result'. If 'point' is 'TRUE', then DDE is enabled, if 'point' is 'FALSE', then DDE is disabled.

```
EnableDDE(TRUE)
```

DDE functions can also be enabled directly without using a point to hold the desired status.

EnableOLE**Syntax**

```
returnstate = EnableOLE(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Pointname</i>	bool point	A Boolean point that holds the required enable/disable state.

Typical Examples

```
EnableOLE(result)
```

OLE functions are enabled based on the value of point 'result'. If result is 'TRUE', then OLE is enabled. If result is 'FALSE', then OLE is disabled.

```
EnableOLE(TRUE)
```

OLE functions can also be enabled directly without using a point to hold the desired status.

EnablePLC**Syntax**

```
returnstate = EnablePLC(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	bool point	A Boolean point that holds the required enable/disable state.

Typical Examples

```
EnablePLC(result)
```

PLC functions are enabled based on the value of point 'result'. If result is 'TRUE', then PLC functions are enabled. If result is 'FALSE', then they are disabled.

```
EnablePLC(TRUE)
```

PLC functions can also be enabled directly without using a point to hold the desired status.

OpenComponent**Syntax**

```
Returnstate = OpenComponent(ComponentName, PLCName)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>ComponentName</i>	text	A Text point or text constant containing the name of the component to open.
<i>PLCName</i>	text	Text point or text constant containing the name of the PLC that the component to open is attached to.

Typical Examples

```
OpenComponent("PLC Data Monitor", "MyPLC")
```

In this example, the PLC Data Monitor component monitoring the PLC 'MyPLC' is opened.

```
Component = "Performance Monitor"
```

```
PLC = "PLC06"
```

```
OK = OpenComponent(Component, PLC)
```

In this example, the Performance Monitor component monitoring the PLC 'PLC06' is opened. 'OK' is used to determine if the action was successful.

Point Commands

CancelForce

Syntax

```
returnstate = CancelForce(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	Name of point. If the point is an array point then all elements within the array have the CancelForce command applied.

Typical Example

```
CancelForce(point1)
```

The forcing of values on the point 'point1' is cancelled.

References

Refer to PLC operation manuals for a detailed description of Force Set, and Force Reset.

CopyArray

Syntax

```
CopyArray (SourceArray, DestArray)
```

Remarks

Argument	Type	Description
<i>SourceArray</i>	---	Name of point array to copy from.
<i>DestArray</i>	---	Name of point array to copy to.

Typical Example

```
InitArray (DestArray, 0)
```

First initialise 'DestArray'.

```
SourceArray [0] = 1
SourceArray [1] = 2
SourceArray [2] = 3
```

Then, initialise 'SourceArray' to {1, 2, 3}.

```
CopyArray (SourceArray, DestArray)
```

Finally, copy the content of the source array 'SourceArray' to the destination array 'DestArray'.

The two arrays do not have to be the same size as each other, for example if 'DestArray' contains 20 elements, only elements [0], [1] and [2] are set to 1, 2 and 3 respectively, the remaining elements are unchanged i.e. 0's. If 'DestArray' is smaller than 'SourceArray' i.e. it contains two elements then only elements [0] and [1] are set to 1 and 2 respectively.

Note: 'CopyArray' accepts arrays of different type i.e. Boolean arrays can be copied into Real arrays, the only restriction is that Text arrays cannot be copied into numeric arrays and vice-versa.

DisableGroup

Syntax

```
returnstate = DisableGroup(groupname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>groupname</i>	text	Name of the group containing the points to disable.

Typical Example

```
DisableGroup("<Default>")
```

All points belonging to the <Default> group is disabled thus preventing values from being read/written.

DisablePoint

Syntax

```
returnstate = DisablePoint(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Pointname</i>	point	Name of point to be disabled.

Typical Example

```
DisablePoint(point1)
```

The point 'point1' is disabled thus preventing values to be read/written.

Note: This is useful for optimisation of communications.

EnableGroup

Syntax

```
returnstate = EnableGroup(groupname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>groupname</i>	text	Name of the group containing the points to enable.

Typical Example

```
EnableGroup("<Default>")
```

All points belonging to the '<Default>' group is enabled thus allowing values to be read/written.

EnablePoint

Syntax

```
returnstate = EnablePoint(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	Name of point to be enabled.

Typical Example

```
EnablePoint(point1)
```

The point 'point1' is enabled thus allowing values to be read/written.

Force

Syntax

```
returnstate = Force(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	Name of point to have force state applied. If the point is an array point then all elements within the array have the Force command applied.

Typical Example

```
Force(point1)
```

The point 'point1' is locked in its current state. i.e. if it is currently set to 1 it cannot be changed until the forced state is removed via the CancelForce command.

ForceReset**Syntax**

```
returnstate = ForceReset(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	Name of point. If the point is an array point then all elements within the array have the ForceReset command applied.

Typical Example

```
ForceReset(point1)
```

The Boolean point 'point1' has its value set to 'FALSE'.

References

Refer to PLC operation manuals for a detailed description of ForceSet, and ForceReset.

ForceSet**Syntax**

```
returnstate = ForceSet(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	Name of point. If the point is an array point then all elements within the array have the ForceSet command applied.

Typical Example

```
ForceSet(point1)
```

The Boolean point 'point1' has its value set to 'TRUE'.

References

Refer to PLC operation manuals for a detailed description of Force Set, and Force Reset.

GetBit**Syntax**

```
returnpoint = GetBit(pointname,bit)
```

Remarks

Argument	Type	Description
<i>pointname</i>	Integer / real	This is the name of the point to get the bit value from. Indirection or point value may be used.
<i>bit</i>	integer	This specifies which bit to get the value of.
<i>returnpoint</i>	bool	This contains the return value 'TRUE' or 'FALSE'.

Typical Example

```
pointname = 256;  
returnpoint = GetBit(pointname,8)
```

The point 'returnpoint' contains 'TRUE'.

GetPointValue**Syntax**

```
returnpoint = GetPointValue(pointname,offset)
```

Remarks

Argument	Type	Description
<i>pointname</i>	point	This is the name of the point whose contents are to be returned.
<i>offset</i>	integer	This specifies the offset into an array point. 0 if the point is not an array point.
<i>returnpoint</i>	point	Point that contains the return value. The type of data returned is dependant on the pointname specified.

Typical Example

```
pointname = 10;
returnpoint = GetPointValue(pointname,0)
```

The point 'returnpoint' contains the value 10. The offset is added to any offset specified for pointname. For example:

```
returnpoint = GetPointValue(a[10],10)
```

Causes the 21st element (offsets begin at zero) of array 'a' to be retrieved.

Note: It is often simpler to access an array element directly, e.g. returnpoint = a[20].

InitialiseArray**Syntax**

```
InitArray (arrayname, value)
```

Remarks

Argument	Type	Description
<i>arrayname</i>	---	Name of point array.
<i>value</i>	---	Value to set all elements of the array to.

Typical Example

```
InitArray (MyArray, 0)
```

In this example, all elements of the array 'MyArray' are set to 0.

InputPoint**Syntax**

```
returnstate = InputPoint(pointname, returnflag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	The point name whose data is to be read.
<i>returnflag</i>	point	Optional Boolean point which is set to 'TRUE' when value is returned from the PLC.

Typical Examples

```
InputPoint(point)

returnflag = FALSE
InputPoint(point, returnflag)
```

A request is made that the current value of point 'point' should be read. In the second example, returnflag is set to 'TRUE' when the value is returned from the PLC.

Note: The value is not returned immediately - it is not possible to use the returned value in the same script as the InputPoint command. Instead, the value should be accessed from within an "On Condition" script which has an expression of 'returnflag = TRUE'.

OutputPoint**Syntax**

```
returnstate = OutputPoint(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	The point to be updated.

Typical Examples

```
OutputPoint(result)
```

The point 'result' is updated with its current value.

Note: The value of a point connected to a PLC is not be set if the point is currently in a "forced" state.

PointExists**Syntax**

```
returnpoint = PointExists(pointname)
```

Remarks

Argument	Type	Description
<i>pointname</i>	string	This text contains the point name.
<i>returnpoint</i>	point	Boolean point that contains the return value.

Typical Example

```
PointName="Testpoint"
Exists=PointExists(PointName)
```

The Boolean point 'Exists' is set to 'TRUE' if a point called 'TestPoint' exists.

Note: "PointName" is a text point which can be set to any string value.

SetBit**Syntax**

```
returnstate = SetBit(pointname,bit,value)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	integer/ real	This is the name of the point to set the bit for. Indirection or point arrays may be used.
<i>bit</i>	integer	This specifies the bit to set.
<i>value</i>	bool	This specifies the value to set the bit to.

Typical Example

```
testpoint = 0;
SetBit(testpoint,4,TRUE)
```

The point 'testpoint' contains the value 16.

SetPointValue**Syntax**

```
returnstate = SetPointValue(pointname,offset,value)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	point	This is the name of the point whose contents are to be updated. Indirection or point arrays may be used.
<i>offset</i>	integer	This specifies the offset into an array point. 0 if the point is not an array point.
<i>value</i>	Integer / real	The new value that the chosen point is to be updated to.

Typical Example

```
SetPointValue(value,0,10)
```

The point 'value' contains the value 10.

Note: The value of a point connected to a PLC is not set if the point is currently in a "forced" state.

The offset is added to any offset specified for pointname. For instance:

```
SetPointValue(a[10],10,100)
```

Causes the 21st element (offsets begin at zero) of array 'a' to be set to 100. It is often simpler to access an array element directly, for instance:

```
a[20] = 100
```

PLC Commands

ClosePLC

Syntax

```
returnstate = ClosePLC("plcname")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0.
<i>plcname</i>	string	Name of PLC to be opened. If the PLC is being accessed using a communications component, e.g. the Omron CX-Communications Control this parameter should be the control name and PLC name separated by a dot e.g. "OMRONCXCommunicationsControl.controlPLC".

Typical Example

```
ClosePLC("controlPLC")
```

The PLC called controlPLC is closed. No further communications with the PLC will take place until it is reopened.

DownloadPLCProgram**Syntax**

```
returnstate = DownloadPLCProgram(plcname, filename, processed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC to download the program to.
<i>filename</i>	string	Name of the file on disk to download to the PLC. If a drive and path are not specified, the current directory is assumed, which may not be the same as the application directory. If a filename is specified as "" the user is prompted at runtime for a filename.
<i>processed</i>	bool	<i>processed</i> is set to 'TRUE' when the operation is actually completed.

Typical Example

```
DownloadPLCProgram("controlPLC", "Prog01.bin", done)
DO UNTIL done or timeout > 5
  Sleep(10)
  timeout += 0.01
LOOP
```

The program stored in the file 'Prog01.bin' in the current directory is downloaded to the PLC 'controlPLC'. Before continuing, the script waits up to five seconds for the action to succeed.

Note: The operation may not be complete immediately after the statement has been executed. The processed flag 'done' is set at a later time when the operation has been completed. Therefore, if using statements that require the upload to be completed, either wait for the flag to be set (as shown) or create an On Condition script containing the code to be executed after the upload, with the processed flag as the expression (e.g. 'done').

Note: This command can only be used when the PLC is in 'STOP' mode. Refer to chapter 4, GetPLCMode or chapter 4, SetPLCMode for further information.

GetPLCMode

Syntax

```
mode = GetPLCMode("plcname")
```

Remarks

Argument	Type	Description
<i>mode</i>	string	A Text point containing the current PLC mode. Possible modes are 'STOP', 'DEBUG', 'RUN', 'MONITOR' and 'UNKNOWN'.
<i>plcname</i>	string	Name of the PLC.

Typical Example

```
currentmode = GetPLCMode("controlPLC")
```

In this example, the current mode of the PLC 'controlPLC' is stored in the point 'currentmode'.

OpenPLC

Syntax

```
Returnstate = OpenPLC("plcname", processed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0.
<i>plcname</i>	string	Name of PLC to be opened. If the PLC is being accessed using a communications component, e.g. the Omron CX-Communications Control this parameter should be the control name and PLC name separated by a dot e.g. "OMRONCXCommunicationsControl.controlPLC".
<i>processed</i>	bool	Flag set to TRUE when set operation has actually been completed.

Typical Example

```
OpenPLC("controlPLC", doneopen
DO UNTIL doneopen or timeout > 5
  Sleep(10)
  timeout += 0.01
LOOP
```

The PLC called controlPLC is opened for communication.

Note that the PLC may not be opened immediately after the statement has been executed. The *processed* flag will be set at a later time when the operation has been completed. Therefore, if using

statements which require the operation to be completed, either wait for the flag to be set as shown above, or create an On Condition script containing the code to be executed after the PLC is opened with the 'processed' flag as the expression (this is generally more efficient).

PLCCommsFailed

Syntax

```
returnstate = PLCCommsFailed("plcname")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC to be checked.

Typical Example

```
IsFailing = PLCCommsFailed ("controlPLC")
```

The point *IsFailing* is set to true if the PLC called *controlPLC* is currently not communicating. Otherwise it is set to false.

Note: This function returns to TRUE from the time when a communications timeout error with the named PLC occurs, until successful communication with the PLC takes place.

PLCMonitor

Syntax

```
returnstate = PLCMonitor("plcname")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC to be monitored.

Typical Example

```
PLCMonitor("controlPLC")
```

The monitor dialog for the PLC called *controlPLC* is invoked. This dialog can be used to check PLC status, change mode, etc.

SetPLCMode

Syntax

```
returnstate = SetPLCMode("plcname", mode, processed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC.
<i>mode</i>	string	A value for the new PLC mode. Valid modes are 'STOP', 'DEBUG', 'RUN' and 'MONITOR'.
<i>processed</i>	bool	<i>processed</i> is set to 'TRUE' when the operation is actually completed.

Typical Examples

```
SetPLCMode("controlPLC", "STOP", done)
DO UNTIL done or timeout > 5
  Sleep(10)
  timeout += 0.01
LOOP
```

In this example, the mode of the PLC called 'controlPLC' is changed to "STOP". Before continuing, the script waits up to five seconds for the action to succeed.

Note: The mode may not be changed immediately after the statement has been executed. The processed flag 'done' is set at a later time when the operation has been completed. Therefore, if using statements that require the operation to be completed, either wait for the flag to be set (as shown) or create an On Condition script containing the code to be executed after the mode is set, with the processed flag as the expression (e.g. 'done').

SetPLCPhoneNumber

Syntax

```
Returnstate = SetPLCPhoneNumber("plcname", numbertext)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC to change the number of.
<i>numbertext</i>	string	New phone number for the PLC.

Typical Example

```
SetPLCPhoneNumber("controlPLC", "01234 987654")
```

The phone number for the PLC is changed to the required value.

UploadPLCProgram**Syntax**

```
returnstate = UploadPLCProgram(plcname, filename, processed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>plcname</i>	string	Name of PLC to upload the program from.
<i>filename</i>	string	Name of the file on disk to upload the program to. If a drive and path are not specified, the file is created in the current directory, which may not be the same as the application directory. If a filename is specified as "" the user is prompted at runtime for a filename.
<i>processed</i>	bool	<i>processed</i> is set to 'TRUE' when the operation is actually completed.

Typical Example

```
UploadPLCProgram("controlPLC", "Prog01.bin", done)
DO UNTIL done or timeout > 5
  Sleep(10)
  timeout += 0.01
LOOP
```

The program in the PLC 'controlPLC' is uploaded to the file 'Prog01.bin' in the current directory. Before continuing, the script waits up to five seconds for the action to succeed.

Note: The operation may not be complete immediately after the statement has been executed. The processed flag 'done' is set at a later time when the operation has been completed. Therefore, if using statements that require the upload to be completed, either wait for the flag to be set (as shown) or create an On Condition script containing the code to be executed after the upload, with the processed flag as the expression (e.g. 'done').

Note: This command can only be used when the PLC is in 'STOP' mode. Refer to chapter 4, GetPLCMode or chapter 4, SetPLCMode for further information.

Temperature Controller Commands

TCAutoTune

Syntax

```
returnstate = TCAutoTune(TController,mode)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	string	This is a string representing the name of the temperature controller.
<i>mode</i>	point	This is a point depicting the mode of operation and defines the operation to be carried out when a TCAutoTune command is issued. 0: Indicates that the auto-tuning operation is to be stopped. 1: This mode is supported on the E5*K and is used to set the limit cycle of the manipulated variable change width to 40%. 2: This is used to start the auto-tuning operation.

Typical Example

```
temp1 = TCAutoTune("e5ak",temp2)
```

TBackupMode

Syntax

```
returnstate = TBackupMode(TController,mode)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	string	This is a string representing the name of the temperature controller.
<i>mode</i>	point	This is a point depicting the mode of operation and defines the method used by a temperature controller for storing internal variables. 0: In this mode variables are stored in RAM and EPROM. 1: In this mode variables are stored in RAM only.

Typical Example

```
temp1 = TCBackupMode("ea5k",temp2)
```

TCGetStatusParameter

Syntax

```
returnstate = TCGetStatusParameter(TController,paramID,value)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	string	This is a string representing the name of the temperature controller.
<i>paramID</i>	point	This is a point depicting the required parameter range 0 to 22: 0: ControlMode. 1: Output. 2: InputShiftDelay (Bool) E5*F, E5*X, E5*J. 3: DisplayUnit. 4: PIDConstantDisplay (Bool) E5*F, E5*X, E5*J. 5: OutputType. 6: CoolingType. 7: Output2. 8: Alarm1. 9: Alarm2. 10: InputType (Integer) E5*F, E5*X, E5*J. 11: OperationMode. 12: BackupMode. 13: AutoTuneMode. 14: OverFlow (Bool) E5*F, E5*X, E5*J. 15: UnderFlow (Bool) E5*F, E5*X, E5*J. 16: SensorMalfunction (Bool) E5*F, E5*X, E5*J. 17: ADConvertorFailure (Bool) E5*F, E5*X, E5*J. 18: RAMAbnormality (Bool) E5*F, E5*X, E5*J. 19: RAMMismatch (Bool) E5*F, E5*X, E5*J. 20: StatusWordsOnly (Bool) E5*K only (TRUE indicates valid words below). 21: Status0 (word) E5*K only. 22: Status1 (word) E5*K only.
<i>value</i>	point, real or int	The returned status parameter value. Refer to <i>paramID</i> above for details.

Typical Example

```
temp1 = TcGetStatusParameter("e5ak",temp2,temp3)
```

TCRemoteLocal

Syntax

```
returnstate = TCRemoteLocal(TController,mode)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	string	This is a string representing the name of the temperature controller.
<i>mode</i>	point	This is a point depicting the mode of operation and defines the operational mode of a temperature controller. 0: This specifies the temperature controller is in remote mode. 1: This specifies that the temperature controller is in local mode.

Typical Example

```
temp1 = TCRemoteLocal("e5ak", temp2)
```

Note: This command was previously called TCOperationalMode.

TCRequestStatus

Syntax

```
returnstate = TCRequestStatus(Tcontroller, returnflag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	String	This is a string representing the name of the temperature controller.
<i>returnflag</i>	Point	This is a point depicting that the status has been returned and is available for the command TCGetStatusParameter.

Typical Example

```
temp1 = TCRequestStatus("e5ak", temp2)
```

Note: The status information is NOT returned immediately - it is not possible to access the status information in the same script as the TCRequestStatus command. Instead, the status information should be accessed from within an "On Condition" script which has an expression of "returnflag == TRUE".

TCRspLsp**Syntax**

```
returnstate = TCRspLsp(Tcontroller,mode)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	String	This is a string representing the name of the temperature controller.
<i>mode</i>	Point	This is a point depicting the mode of operation and defines the setpoint mode used by the temperature controller. 0: This specifies remote setpoint mode. 1: This specifies local setpoint mode.

Typical Example

```
temp1 = TCRspLsp("e5ak",temp2)
```

Note: This command was previously called TCSetpoint.

TCRunStop**Syntax**

```
returnstate = TCRunStop(TController,mode)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	string	This is a string representing the name of the temperature controller.
<i>mode</i>	point	This is a point depicting the mode of operation and defines either auto-output mode shift or manual output mode shift. 0: This specifies manual output mode shift. 1: This specifies auto-output mode shift.

Typical Example

```
temp1 = TCRunStop("e5ak",temp2)
```

Note: This command was previously called TCMoDeShift.

TCSaveData**Syntax**

```
returnstate = TCSaveData(TController)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	String	This is a string representing the name of the temperature controller.

Typical Example

```
temp1 = TCSaveData("e5ak",temp2)
```

TCSettingLevel1**Syntax**

```
returnstate = TCSettingLevel1(TController)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	String	This is a string representing the name of the temperature controller.

Typical Example

```
temp1 = TCSettingLevel1("e5ak")
```

TCReset**Syntax**

```
returnstate = TCReset(TController)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>TController</i>	String	This is a string representing the name of the temperature controller.

Typical Example

```
temp1 = TCReset("e5ak")
```

DDE Commands**DDEExecute****Syntax**

```
returnstate = DDEExecute(channel, {command})
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command. Both server and topic parameters applied to the channel based on the DDEInitiate() command must be open or an error is reported.
<i>command</i>	String	This is a <i>command</i> as recognised by the server application specified within the <i>channel</i> .

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
DDEExecute(channelname, {[OPEN("C:\EXCEL\WORK\SHEET2.XLS")]} )
```

The file 'SHEET2.XLS' within path 'C:\EXCEL\WORK' is opened in Microsoft Excel, as specified by the Integer point 'channelname'. The file 'SHEET1.XLS' is already open in Microsoft Excel.

DDEInitiate**Syntax**

```
channel = DDEInitiate("server", topic)
```

Remarks

Argument	Type	Description
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command.
<i>server</i>	String	This contains the application that supports DDE as a DDE server. Typically, this is the name of the applications' *.EXE executable file without the filename extension. At runtime, the <i>server</i> application must be open or a value cannot be returned and an error is reported.
<i>topic</i>	String	This contains the name of the topic recognised by the <i>server</i> application. Typically, a topic is a document within an application. At runtime, the <i>topic</i> must be open or a value cannot be returned and an error is reported. The <i>topic</i> may be left empty, which enables documents to open remotely prior to making a specified connection. The <i>topic</i> name 'System' may be used to find out which other topics within the <i>server</i> application are available. However, this is dependant on the <i>server</i> application supporting this <i>topic</i> .

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
```

The Integer point 'channelname' is provided with a DDE link to the application Microsoft Excel which is run by the executable filename 'EXCEL.EXE', and to the file 'SHEET1.XLS' within that application.

DDEOpenLinks

Syntax

```
returnstate = DDEOpenLinks(channel)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command. Both server and topic parameters applied to the channel in the DDEInitiate() command must be open or an error is reported.

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
DDEOpenLinks(channelname)
```

The DDEOpenLinks command enables points which have been configured to communicate via DDE to begin data transfer. Data transfer between CX-Supervisor and the application Microsoft Excel is automatically maintained until the channel is closed either by Microsoft Excel or by the command DDETerminate() using the Integer point 'channelname', or the command DDETerminateAll().

DDEPoke

Syntax

```
returnstate = DDEPoke(channel, "item", pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command. Both server and topic parameters applied to the in the DDEInitiate() command must be open or an error is reported.
<i>item</i>	string	This is an item as recognised by the server application. For instance, a cell is an <i>item</i> within a spreadsheet application. Likewise, a page is an <i>item</i> for a word processing application. It is wholly dependant on the server application
<i>pointname</i>	point	This is a point whose attributes must include a DDE Access of 'Read/Only' or 'Read/Write'. The contents of this point are assigned to the server application.

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
DDEPoke(channelname, "R2C5", data)
```

The content of point 'data' is sent to row 2, column 5 of 'SHEET1.XLS' in the Microsoft Excel application. The Microsoft Excel application, and 'SHEET1.XLS' are specified by Integer point 'channelname'.

References

Refer to the *CX-Supervisor User Manual* for details of DDE Access.

DDERequest

Syntax

```
pointname = DDERequest(channel, "item")
```

Remarks

Argument	Type	Description
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command. Both server and topic parameters applied to the channel in the DDEInitiate() command must be open or an error is reported.
<i>item</i>	string	This is an item as recognised by the server application. For instance, a cell is an <i>item</i> within a spreadsheet application. Likewise, a page is an <i>item</i> for a word processing application. It is wholly dependant on the server application.
<i>pointname</i>	point	This is a point whose attributes must include a DDE Access of 'Read/Write'.

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
cellref = DDERequest("channelname", "R2C5")
```

The point 'cellref' is filled from a specific item, row 2, column 5 from 'SHEET1.XLS' from the Microsoft Excel application, specified by the Integer point 'channelname'.

References

Refer to the *CX-Supervisor User Manual* for details of DDE Access.

DDETerminate**Syntax**

```
returnstate = DDETerminate(channel)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>channel</i>	Integer point	This is an integer point which contains the return value of the DDEInitiate() command. Both server and topic parameters applied to the channel in the DDEInitiate() command must be open or an error is reported.

Typical Example

```
DDETerminate(channelname)
```

The server and topic specified by Integer point 'channelname' is closed.

DDETerminateAll

Syntax

```
returnstate = DDETerminateAll()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
DDETerminateAll()
```

All previously initiated DDE links are closed.

Alarm Commands

AcknowledgeAlarm

Syntax

```
returnstate = AcknowledgeAlarm("alarmname")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>alarmname</i>	string	This is the identifier of the alarm.

Typical Example

```
AcknowledgeAlarm("temphigh")
```

The alarm 'temphigh' is acknowledged.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

AcknowledgeAllAlarms

Syntax

```
returnstate = AcknowledgeAllAlarms()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
AcknowledgeAllAlarms()
```

All alarms are acknowledged.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

AcknowledgeLatestAlarm**Syntax**

```
returnstate = AcknowledgeLatestAlarm()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
AcknowledgeLatestAlarm()
```

The most current alarm of the highest priority is acknowledged.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

ClearAlarmHistory**Syntax**

```
returnstate = ClearAlarmHistory()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
ClearAlarmHistory()
```

The alarm history window is cleared and the log is cleared.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

CloseAlarmHistory**Syntax**

```
returnstate = CloseAlarmHistory()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
CloseAlarmHistory()
```

The alarm history window is closed.

References

Refer to the *CX-Supervisor User Manual* for details of alarms

CloseAlarmStatus**Syntax**

```
returnstate = CloseAlarmStatus()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
CloseAlarmStatus()
```

The current alarm status window is closed.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

DisplayAlarmHistory**Syntax**

```
returnstate = DisplayAlarmHistory()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
DisplayAlarmHistory()
```

The alarm history window is displayed.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

DisplayAlarmStatus**Syntax**

```
returnstate = DisplayAlarmStatus()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
DisplayAlarmStatus()
```

The current alarm status is displayed.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

EnableAlarms

Syntax

```
EnableAlarms (flag, "message")
```

Remarks

Argument	Type	Description
<i>flag</i>	---	If set 'TRUE' then alarm logging is enabled. If set 'FALSE' logging is disabled.
<i>message</i>	---	Text message which is recorded in the alarm log to indicate change of status.

Typical Example

```
EnableAlarms (TRUE, "Alarm logging enabled")
```

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

IsAlarmAcknowledged

Syntax

```
pointname = IsAlarmAcknowledged("alarmname")
```

Remarks

Argument	Type	Description
<i>pointname</i>	bool point	The Boolean point name to be assigned a value based on the test of an acknowledged alarm.
<i>alarmname</i>	string	The identifier of the alarm.

Typical Example

```
acknowledged = IsAlarmAcknowledged("temptoohigh")
```

The point 'acknowledged' is assigned Boolean state "TRUE" if the 'temptoohigh' alarm is currently acknowledged. The point is assigned Boolean state 'FALSE' if the alarm is not currently acknowledged.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

IsAlarmActive

Syntax

```
pointname = IsAlarmActive("alarmname")
```

Remarks

Argument	Type	Description
<i>pointname</i>	bool point	The Boolean point name to be assigned a value based on the test of an active alarm.
<i>alarmname</i>	string	The identifier of the alarm.

Typical Example

```
active = IsAlarmActive("temptoohigh")
```

The point 'active' is assigned Boolean state "TRUE" if the 'temptoohigh' alarm is currently active. The point is assigned Boolean state 'FALSE' if the alarm is not currently active.

References

Refer to the *CX-Supervisor User Manual* for details of alarms.

File Commands

CloseFile

Syntax

```
returnstate = CloseFile(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	bool	A Boolean point that holds the required status of whether blank spaces should be stripped from the file when it is closed.

Typical Examples

```
CloseFile(status)
```

The currently open file is closed. Blank spaces at the end of each line are stripped from the file if the Boolean point 'status' is set to 'TRUE'.

```
CloseFile(FALSE)
```

In this example, the currently open file is closed and any blank spaces are not stripped from the file.

Note: If blank spaces are stripped from the file, then it greatly reduces in size but it takes slightly longer to close. Blank spaces should not be stripped from the file if it is being used on a network drive by more than one system at a time.

CopyFile

Syntax

```
returnstate = CopyFile("sourcename", "destname")
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise
<i>sourcename</i>	string	Pathname of file to be copied. May include a "*" wildcard character.
<i>destname</i>	string	Pathname of destination of copy. If path name does not exist it is created.

Typical Example

```
CopyFile("c:\autoexec.bat", "c:\autoexec.old")
```

The file "c:\autoexec.bat" is copied to the file "c:\autoexec.old".

```
CopyFile("c:\logging\*.dlv", "a:\backup")
```

The data log files (ending in dlv) in "C:\logging" are copied to the "\backup" directory on drive A:

DeleteFile

Syntax

```
returnstate = DeleteFile("filename")
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Filename</i>	string	Pathname of file to be deleted.

Typical Example

```
DeleteFile("c:\pagename.pag")
```

The file "c:\pagename.pag" is deleted.

EditFile

Syntax

```
returnstate = EditFile("filename")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>filename</i>	string	Pathname of the file to be edited.

Typical Example

```
EditFile("C:\report3.txt")
```

FileExists

Syntax

```
returnpoint = FileExists (filename)
```

Remarks

Argument	Type	Description
<i>filename</i>	string	This text string contains the file name.
<i>returnpoint</i>	point	Boolean point that contains the return value.

Typical Example

```
FileName = "TEST.TXT"
Exists = FileExists(FileName)
```

The Boolean point 'Exists' is set to 'TRUE' if a file called 'C:\TEST.TXT' exists.

Note: "FileName" is a text point which can be set to any string value.

MoveFile

Syntax

```
returnstate = MoveFile("sourcename", "destname")
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>sourcename</i>	string	Pathname of file to be moved.
<i>destname</i>	string	Pathname of destination of move.

Typical Example

```
MoveFile("c:\autoexec.bat", "c:\autoexec.old")
```

The file "c:\autoexec.bat" is moved to the file "c:\autoexec.old".

OpenFile**Syntax**

```
returnstate = OpenFile("filename")
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Filename</i>	string	Pathname of file to be opened.

Typical Example

```
OpenFile("c:\filename.csf")
```

The file "c:\filename.csf" is opened and able to be accessed by the Read() and Write() script commands. Only one file can be open at a time. Files can be shared (for instance located on a network drive, and accessed by several running CX-Supervisor applications simultaneously - this can be used for data exchange).

PrintFile**Syntax**

```
returnstate = PrintFile("filename")
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Filename</i>	string	Pathname of file to be printed.

Typical Example

```
PrintFile("c:\autoexec.bat")
```

The file "c:\autoexec.bat" is sent to the currently configured printer.

Script commands that have textual arguments can take either literal strings within quotes or text points.

Note: CX-Supervisor uses the OLE registration information (file extension associations) to decide how to print a file. It invokes the parent application associated with a particular file extension, instructing the application to start minimised and passing the "print" command. For example, if the file extension .txt is associated with Notepad, then Notepad is invoked to print the file.

Read**Syntax**

```
returnstate = Read(RecordId, pointname, ...)
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>RecordId</i>	integer	An index into the file.
<i>Pointname</i>	point	Name(s) of point(s) to be updated with the data read from the open file.

Typical Examples

```
Read(1, value)
```

The point 'value' is loaded with the value read from the currently open file using the value of 1 as an index into the file.

```
ReadOK = Read(indexno, value1, value2, value3)
```

The points 'value1', 'value2', 'value' are loaded using the value of indexno as an index into the file. Pass or fail status is stored in 'ReadOK'.

Note: It is advisable to use a RecordId less than 1024 whenever possible, in order to optimise file access time (records 0 to 1023 are cached).

ReadMessage**Syntax**

```
returnstate = ReadMessage("filename", offset, textpoint, noofchars)
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Filename</i>	string	Pathname of file to be read.
<i>Offset</i>	integer	An offset from the beginning of the file (in characters) indicating where to start reading from.
<i>Textpoint</i>	text point	The text point which holds the characters read from the file.
<i>Noofchars</i>	integer	The number of characters to read from the file.

Typical Example

```
ReadMessage ("C:\CX-SUPERVISOR\TESTFILE.TXT", 0, TextPoint, 20)
```

The first 20 characters are be read from the file "C:\CX-SUPERVISOR\TESTFILE.TXT" and stored in the point 'TextPoint'.

Note: Text points can hold up to 256 characters therefore a maximum of 256 characters can be read from the file.

SelectFile**Syntax**

```
filename = SelectFile ()
```

A file open dialog is displayed which allows the user to select a file. The resulting filename is copied into filename.

Remarks

Argument	Type	Description
<i>Filename</i>	---	Text string returned. Contains fully qualified filename including drive and path if OK was selected from OpenFileDialog, otherwise contains empty string.

Write**Syntax**

```
returnstate = Write(RecordId, pointname, ...)
```

Remarks

Argument	Type	Description
<i>Returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>RecordId</i>	integer	An index into the file.
<i>Pointname</i>	point	Name(s) of point(s) containing data to write to the open file.

Typical Examples

```
WroteOK = Write(indexno, $Second)
```

The point '\$Second' is written to the currently open file using the value of indexno as an index into the file. Pass or fail status is stored in 'WroteOK'.

```
Write(2, $Second, $Minute, $Hour)
```

The points '\$Second', '\$Minute', '\$Hour' are written to the currently open file using the value 2 as an index into the file.

Note: It is advisable to use a RecordId less than 1024 whenever possible, in order to optimise file access time (records 0 to 1023 are cached).

WriteMessage**Syntax**

```
returnstate = WriteMessage("filename", offset, "text", linefeed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>filename</i>	string	Pathname of file to be written.
<i>offset</i>	integer	An offset from the beginning of the file (in characters) indicating where to start writing. If the offset is -1 then the message is appended to the end of the file.
<i>text</i>	string	The text to be written into the file.
<i>linefeed</i>	bool	A flag to indicate a carriage return and line feed should be appended.

Typical Example

```
WriteMessage("C:\CX-SUPERVISOR\TESTFILE.TXT", 0, "Hello World", TRUE)
```

The text 'Hello World' is written at the start of the 'C:\CX-SUPERVISOR\TESTFILE.TXT' file and a carriage return and line feed is appended which moves and subsequent text to the start of the next line.

Note: When the text is written into the file it overwrites any existing text that may exist at this location.

Graph Commands

ClearGraph

Syntax

```
returnstate = ClearGraph("graphid", "pagename")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trend or scatter graph to be cleared.
<i>pagename</i>	string	Optional parameter indicating the name of the page that the graph is on.

Typical Examples

```
ClearGraph("Graph_1", "TestPage1")
```

The trend or scatter graph on 'TestPage1' with the identifier 'Graph_1' has its data cleared.

```
ClearGraph ("Graph_2")
```

The trend or scatter graph on the current page, with the identifier 'Graph_2', has its data cleared.

EditGraph

Syntax

```
returnstate = EditGraph("graphid")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trendgraph to be edited.

Typical Example

```
EditGraph( "Graph_1" )
```

The Edit Graph dialog is displayed offering options to view historical data for the chosen trend graph.

- ◆ **Display Data** loads the currently selected data sample i.e. either the current screen data or a snapshot of the data, into the trend graph.
- ◆ **Snapshot** stores the current data buffer associated with the trend graph. The snapshot is given a timestamped default description.
- ◆ **Description** provides the ability to change the description associated with the snapshot.
- ◆ **Import Data** provides the ability to load in a previously saved trend graph file.
- ◆ **Export Data** provides the ability to store a snapshot to a file, either in internal CX-Supervisor format, or as a text file that can be imported into other applications.
- ◆ **Delete** removes the currently selected snapshot.

Note: This command is provided for compatibility with SCS v2.0 applications. For newer applications the data logging facilities should be used in preference.

SaveGraph**Syntax**

```
returnstate = SaveGraph( "graphid" )
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trend to be saved.
<i>pagename</i>	string	<i>Optional</i> parameter indicating the name of the page that the graph is on.

Typical Examples

```
SaveGraph( "Graph_1", "TestPage1" )
```

The trend graph on the page 'TestPage' with the identifier 'Graph_1' has its data saved to disc.

```
SaveGraph( "Graph_2" )
```

The trend graph on the current page with the identifier 'Graph_2' has its data saved to disc.

Snapshot**Syntax**

```
returnstate = Snapshot( "graphid", "pagename" )
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trend graph to have a snapshot
<i>pagename</i>	string	<i>Optional</i> parameter indicating the name of the page that the graph is on.

Typical Examples

```
Snapshot("Graph_1", "TestPage1")
```

The current data in trend graph 'Graph1' on 'TestPage1', is stored and is able to be viewed via the EditGraph command.

```
Snapshot("Graph_2")
```

The current data in trend graph 'Graph1' on the current page, is stored and is able to be viewed via the EditGraph command.

Note: This command is provided for compatability with SCS v2.0 applications. For newer applications the data logging facilities should be used in preference.

StartGraph**Syntax**

```
returnstate = StartGraph("graphid", "pagename")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trend or scatter graph to be started.
<i>pagename</i>	string	<i>Optional</i> parameter indicating the name of the page that the graph is on.

Typical Examples

```
StartGraph("Graph_1", "TestPage1")
```

The trend or scatter graph on 'TestPage1' with the identifier 'Graph_1' has its data logging started.

```
StartGraph("Graph_2")
```

The trend or scatter graph on the current page with the identifier 'Graph_2' has its data logging started.

Note: This command is provided for compatability with SCS v2.0 applications. For newer applications the data logging facilities should be used in preference.

StopGraph

Syntax

```
returnstate = StopGraph("graphid", "pagename")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>graphid</i>	string	The identifier of the trend or scatter graph to be stopped.
<i>pagename</i>	string	<i>Optional</i> parameter indicating the name of the page that the graph is on.

Typical Examples

```
StopGraph("Graph_1", "TestPage1")
```

The trend or scatter graph on 'TestPage1' with the identifier 'Graph_1' has its data logging stopped.

```
StopGraph("Graph_2")
```

The trend or scatter graph on the current page with the identifier 'Graph_2' has its data logging stopped.

Recipe Commands

DisplayRecipes

Syntax

```
returnstate = DisplayRecipes()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
DisplayRecipes()
```

The current recipes is displayed.

References

Refer to the *CX-Supervisor User Manual* for details of recipes.

DownloadRecipe

Syntax

```
returnstate = DownloadRecipe("recipeName")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>recipeName</i>	string	The name of the recipe to be downloaded.

Typical Example

```
DownloadRecipe("recipe1")
```

The recipe 'recipe1' is downloaded.

References

Refer to the *CX-Supervisor User Manual* for details of recipes.

UploadRecipe

Syntax

```
returnstate = UploadRecipe("recipeName", processed)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>recipeName</i>	string	The name of the recipe to be uploaded.
<i>processed</i>	bool	Flag set to true when operation has been completed.

Typical Example

```
UploadRecipe("recipe1", done)
```

The recipe 'recipe1' is uploaded, and point 'done' is set True when the upload is complete.

References

Refer to the *CX-Supervisor User Manual* for details of recipes.

Report Commands

GenerateReport

Syntax

```
returnstate =
  GenerateReport(ReportTemplateFile,ReportOutputFile)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>ReportTemplateFile</i>	string	Pathname of the report template file.
<i>ReportOutputFile</i>	string	Pathname of the report output file.

Typical Example

```
GenerateReport("report3.txt", "output.txt")
```

PrintReport

Syntax

```
returnstate = Printreport(ReportTemplateFile)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>ReportTemplateFile</i>	string	Pathname of the report template file.

Typical Example

```
PrintReport("report3.txt")
```

The ReportTemplateFile report3.txt contains a predefined set of point names and text laid out exactly as the report reader likes to view them. The point names contained within enclosing characters are the CX-Supervisor names for the data that is required in the report.

The enclosing characters can be changed in the Project/Runtime Setting/Report setting dialog box, but once set must be fixed for all reports generated by the project.

The file can be written using any ASCII text editor, for instance a Text file (.TXT), a Rich Text file (.RTF) or a Hypertext file (.HTML).

Examples of the way in which text is changed:

```
The shift foreman was ((ShiftForeman))
```

Becomes:

```
The shift foreman was Fred Smith
The shift output was ((ShiftOutput)) litres
```

Becomes:

```
The shift output was 5000 litres
```

Format specifiers can be used:

```
%s for text string points;
%d for integer points;
%f for real floating points.
```

Where 'MyTextpoint="Hello"':

```
The text of ("My text point is %s",Mypoint))
```

Becomes:

```
The text of My text point is Hello
```

Where MyRealpoint=5467.7658:

```
To two decimal places the value of MyRealpoint is
("%4.2f",MyRealpoint))
```

Becomes:

```
To two decimal places the value of MyRealpoint is 5467.76
```

Combinations of format specifiers are possible:

```
((%s to two decimal places the value of MyRealpoint is
%4.2f",MyTextpoint,MyRealpoint))
```

Becomes:

```
Hello to two decimal places the value of MyRealpoint is 5467.76
```

ViewReport

Syntax

```
returnstate = ViewReport(ReportTemplateFile)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>ReportTemplateFile</i>	string	Pathname of the report template file.

Typical Example

```
ViewReport("report3.txt")
```

Text Commands

BCD

Syntax

```
result = BCD (value)
```

Remarks

Argument	Type	Description
<i>Value</i>	---	Number to convert to Binary Coded Decimal (BCD).
<i>result</i>	---	String containing BCD representation of <i>value</i> .

Typical Example

```
BCDStr = BCD(39)
```

In this example, 'BCDstr' contains '00111001'.

Bin

Syntax

```
result = Bin (value)
```

Remarks

Argument	Type	Description
<i>value</i>	---	Number to be converted to a binary number.
<i>result</i>	---	String containing binary representation of <i>value</i> .

Typical Example

```
BStr = Bin (20)
```

In this example, 'Bstr' contains '10100'.

Chr

Syntax

```
result = Chr (value)
```

Remarks

Argument	Type	Description
<i>value</i>	---	Extended ASCII value to convert to a character.
<i>result</i>	---	String containing single character representation of <i>value</i> .

Typical Example

```
Char = Chr(65)
```

In this example, 'Char' contains 'A'.

FormatText**Syntax**

```
textpoint = FormatText ("formattext", expression, ...)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text point	A text point which holds the formatted text.
<i>formattext</i>	string	The text (with appropriate formatting characters) that the result <i>expression</i> is inserted into.
<i>expression</i>	Integer / real	The value(s) or expression(s) that is inserted into <i>formattext</i> .

Typical Examples

```
TextPoint = FormatText ("Boiler temperature is %ld degrees.",  
BoilerTemp)
```

The value of the 'BoilerTemp' point is inserted into the specified text at the position marked by the formatting characters (%ld) and then stored in the point 'TextPoint'.

If the value of 'BoilerTemp' was 57 then the resultant text that is stored in 'TextPoint' is as follows:

```
"Boiler temperature is 57 degrees."
```

```
TextPoint = FormatText ("Boiler %ld temperature is %ld degrees.",  
BoilerNo, BoilerTemp)
```

The value of 'BoilerNo' point is inserted at the first '%ld' marker and the value of the 'BoilerTemp' point is inserted at the second '%ld' marker and the resulting string is stored in the point 'TextPoint'.

If the value of 'BoilerNo' was 7 and the value of 'BoilerTemp' was 43 then the resultant text stored in the 'TextPoint' is as follows:

```
"Boiler 7 temperature is 43 degrees."
```

Note: The formatting characters are standard 'C' formatting characters (as used by the C-language `printf` function). Some commonly used types are:

- ◆ %ld. Insert integer value;
- ◆ %f. Insert decimal value. Prefix with decimal point and number to control position (for instance '%.2f' for 2 decimal places);
- ◆ %s. Insert string;
- ◆ %IX. Insert hexadecimal value (upper case HEX characters, for instance 'FFFF');
- ◆ %lx. Insert hexadecimal value (lower case HEX characters, for instance 'ffff');
- ◆ %c. Insert character (can be used to convert value to character, for instance to insert control character).

With the text left aligned, and with a width field (for instance '%-6ld' to insert a value left aligned with a field 6 characters wide).

References

More complex expressions (for instance controlling justification, decimal places, number base, etc.) are also possible. Refer to any C language reference book for full details of the format used by the 'printf' function.

GetTextLength

Syntax

```
value = GetTextLength (textpoint)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text	This is the point which has its text length counted.
<i>returnpoint</i>	Integer / real	This is the point that holds the return <i>value</i> .

Typical Example

```
textpoint = "Hello World"
count = GetTextLength (textpoint)
```

The number of characters in 'textpoint' is counted and the point 'count' is set to the value 11.

Hex

Syntax

```
result = Hex (value)
```

Remarks

Argument	Type	Description
<i>Value</i>	---	Number to be converted to a Hex number.
<i>Result</i>	---	String containing Hex representation of <i>value</i> .

Typical Example

```
HStr = Hex (44)
```

In this example, 'Hstr' contains '2C'.

Left**Syntax**

```
lefttext = Left(textpoint,noofchars)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text	The text point containing the string that is to be manipulated.
<i>noofchars</i>	integer	The number of characters to extract from the start of the string.
<i>lefttext</i>	text	Text point containing the specified range of characters.

Typical Example

```
textpoint = "abcdefgh"
lefttext = Left(textpoint,3)
```

The text point 'lefttext' contains the string 'abc'.

Message**Syntax**

```
Message("message")
```

Remarks

Argument	Type	Description
<i>message</i>	string	Contains the text string that is displayed in the message box.

Typical Example

```
Message("this is a message")
```

The message 'this is a message' is displayed in a Message Box.

Mid

Syntax

```
midtext = Mid(textpoint,offset,noofchars)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text	The text point containing the string that is to be manipulated.
<i>offset</i>	integer	The zero based index of the first character in the string that is to be included in the extract.
<i>noofchars</i>	integer	The number of characters to extract from the string.
<i>midtext</i>	text	Text point containing the specified range of characters.

Typical Example

```
textpoint = "abcdefgh"
midtext = Mid(textpoint,3,2)
```

The text point 'midtext' contains the string 'de'.

PrintMessage

Syntax

```
PrintMessage ("message")
```

Remarks

Argument	Type	Description
<i>message</i>	string	Contains the text string that is sent to the printer.

Typical Example

```
PrintMessage ("Print this message")
```

The message 'print this message' is printed to the configured 'Alarm/message printer', queued if operating in page mode, or printing has been disabled by the EnablePrinting command.

References

Refer to the *CX-Supervisor User Manual* for further details to configure the 'Alarm/message printer'.

Right

Syntax

```
righttext = Right(textpoint,noofchars)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text	The text point containing the string that is to be manipulated.
<i>noofchars</i>	integer	The number of characters to extract from the end of the string.
<i>righttext</i>	integer	Text point containing the specified range of characters.

Typical Example

```
textpoint = "abcdefgh"
righttext = Right(textpoint, 3)
```

The text point 'righttext' contains the string 'fgh'.

TextToValue**Syntax**

```
valuepoint = TextToValue(textpoint)
```

Remarks

Argument	Type	Description
<i>textpoint</i>	text	The text point containing the string that is to be converted into a number.
<i>valuepoint</i>	integer	A point containing the value returned after conversion from a string.

Typical Examples

```
textpoint = "10"
valuepoint = TextToValue(textpoint)
```

The value 10 is assigned to the point 'valuepoint'.

```
textpoint = "10.34"
realpoint = TextToValue(textpoint)
```

The real value 10.34 is assigned to the real point 'realpoint'.

ValueToText**Syntax**

```
textpoint = ValueToText(value)
```

Remarks

Argument	Type	Description
<i>value</i>	integer	The number that is to be placed into the textpoint. A point name is also a valid parameter.
<i>textpoint</i>	text point	A text point containing the value converted into a string.

Typical Examples

```
textpoint = ValueToText(10)
```

The value 10 is put into a string and assigned to the text point 'textpoint'.

```
value = 10
```

```
textpoint = ValueToText(value)
```

This has the same effect as the previous example.

Event/Error Commands

ClearErrorLog

Syntax

```
ClearErrorLog()
```

Typical Example

```
ClearErrorLog()
```

The error list is cleared and the log deleted.

CloseErrorLog

Syntax

```
returnstate = CloseErrorLog()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
CloseErrorLog()
```

The list of all currently logged errors is closed.

DisplayErrorLog

Syntax

```
returnstate = DisplayErrorLog()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
DisplayErrorLog()
```

A list of all currently logged errors is displayed in a dialog.

EnableErrorLogging

Syntax

```
returnstate = EnableErrorLogging(pointname)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pointname</i>	bool	A Boolean point.

Typical Example

```
EnableErrorLogging(flag)
```

Error Logging is enabled based on the Boolean point 'flag'. If 'flag' is 'TRUE', then error logging is enabled. If 'flag' is false, then error logging is disabled.

LogError

Syntax

```
returnstate = LogError("message", priority)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>message</i>	string	Contains the text string that is displayed in the Error Log.
<i>priority</i>	integer	Priority assigned to the error. 0 - low 1- medium 2- high.

Typical Example

```
LogError("This is an error", 1)
```

The message 'This is an error' appears as a medium priority error in the error log.

LogEvent**Syntax**

```
returnstate = LogEvent("message")
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>message</i>	string	Contains the text string that is displayed in the Error Log.

Typical Example

```
LogEvent("this is an event")
```

The message 'this is an event' appears as an event in the error log.

Printer Commands**ClearSpoolQueue****Syntax**

```
returnstate = ClearSpoolQueue()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
ClearSpoolQueue()
```

Any messages (typically printed alarms) that are queued up waiting to be sent to the CX-Supervisor Alarm/Message printer is discarded.

EnablePrinting**Syntax**

```
returnstate = EnablePrinting(flag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>flag</i>	bool	0 to disable, 1 to enable.

Typical Example

```
EnablePrinting(FALSE) - Disables printing
EnablePrinting(TRUE) - Enables printing
```

While alarm printing is disabled, any new messages are stored but not printed. When alarm printing is re-enabled, any pending messages are printed (if in line mode) or added to the current page (if in page mode).

GetSpoolCount**Syntax**

```
returnstate = GetSpoolCount()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	int	Number of messages queued up waiting to be printed on Alarm/Message printer.

Typical Example

```
NumberMessages = GetSpoolCount()
```

The count of the number of messages (typically printed alarms) that are queued up waiting to be sent to the CX-Supervisor Alarm/Message printer is returned.

PrintActivePage**Syntax**

```
returnstate = PrintActivePage(flag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>flag</i>	bool	Flag is to indicate whether the print setup dialog is to be displayed before printing.

Typical Example

```
PrintActivePage(TRUE)
```

The currently active page is sent to the printer. The flag 'TRUE' indicates that the print dialog is displayed. 'FALSE' causes the print dialog not to be shown.

PrintPage**Syntax**

```
returnstate = PrintPage ("pagename", flag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>pagename</i>	string	The name of the page to be printed.
<i>flag</i>	bool	Flag to indicate whether the print setup dialog is to be displayed before printing.

Typical Example

```
PrintPage("page1", TRUE)
```

The CX-Supervisor page is sent to the printer. The flag 'TRUE' indicates that the print dialog is displayed first to allow for printer configuration. If 'FALSE' was specified instead of 'TRUE' then the print dialog is not shown, the page is just printed.

PrintScreen

Syntax

```
returnstate = PrintScreen(flag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>flag</i>	bool	Flag to indicate whether the print setup dialog is to be displayed before printing.

Typical Example

```
PrintScreen(FALSE)
```

All CX-Supervisor pages currently on view is printed. The flag 'FALSE' indicates that the print dialog is not displayed. A flag of 'TRUE' causes the print dialog to be shown, allowing the user to configure or choose the printer.

PrintSpoolQueue

Syntax

```
returnstate = PrintSpoolQueue()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
PrintSpoolQueue
```

Any message (typically printed alarms) that are queued up waiting to be sent to the CX-Supervisor Alarm/Message printer is printed immediately.

SetPrinterConfig

Syntax

```
returnstate StePrintConfig(Driver, Device, Port)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.
<i>Driver</i>	String	Name of printer device (e.g. "Epson9" for 9 pin Epson printers).
<i>Device</i>	String	Name of specific device (e.g. "Epson FX-870"). This is optional.
<i>Port</i>	String	Name of port or file(e.g. "LPT1:").
<i>Line Terminator</i>	String	Optional. Sets terminator (e.g. cr) to be added to end of each printed line.

Typical Examples

```
SetPrinterConfig("SCSPRN", "", "LPT1:")
```

This uses standard CX-Supervisor line print driver.

```
SetPrinterConfig("", "", "")
```

This uses default Windows printer driver.

```
SetPrinterConfig("Epson9", "", "LPT2:")
```

This uses Epson printer driver, attached to LPT2.

```
SetPrinterConfig(DriverNamePoint, DeviceNamePoint, PrintNamePoint)
```

This uses text points.

```
Terminator = FormatText("%c%c", 13, 10)
```

Character 10 is 'lf' (newline), character 13 is cr (carriage return).

```
SetPrinterConfig("Epson9", "", "LPT1:", Terminator)
```

Security Commands**Login****Syntax**

```
returnstate = Login()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
Login()
```

The Login dialog is displayed for user entry.

References

Refer to the *CX-Supervisor User Manual* for details of Login.

Logout**Syntax**

```
returnstate = Logout()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
Logout()
```

The user is logged out.

References

Refer to the *CX-Supervisor User Manual* for details of Logout.

Setup Users**Syntax**

```
returnstate = SetupUsers()
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	<i>Returnstate</i> is '1' if the function is successful, or '0' otherwise.

Typical Example

```
SetupUsers()
```

The Setup Users dialog is displayed for user entry.

References

Refer to the *CX-Supervisor User Manual* for details of setting and modifying user details.

Data Logging Commands

ClearLogFile

Syntax

```
ClearLogFile("datasetname")
```

Remarks

Argument	Type	Description
datasetname	string	Name of Data Set to clear as text point or constant.

Typical Example

```
ClearLogFile("Process 1")
```

This command will clear all data from the active (latest) log file for this data set, and add a 'Clear Event' indicator.

CloseLogFile

Syntax

```
CloseLogFile("datasetname")
```

or

```
CloseLogFile("databaselink")
```

Remarks

Argument	Type	Description
<i>datasetname</i>	text	Name of Data Set to close as text point or constant.
<i>databaselink</i>	text	Name of Database link to close as text point or constant.

Typical Example

```
CloseLogFile("Process 1")
```

This command will close the active log file for the data set. Logging for this data set is automatically stopped.

CloseLogView

Syntax

```
CloseLogView("datasetname")
```

Remarks

Argument	Type	Description
datasetname	string	Name of Data Set view to close as text point or constant.

Typical Example

```
CloseLogView("Process 1")
```

This command will close the Data Log Viewer, which is displaying the named data set.

ExportAndViewLog**Syntax**

```
ExportAndViewLog ("datasetname", "item list", "format", file,  
outputfile)
```

or

```
ExportAndViewLog ("datasetname", TextArray, "format", file,  
outputfile)
```

Remarks

Argument	Type	Description
datasetname	string	Name of Data Set to export as text point or constant.
item list	string	List of Items and/or Groups within the data set to export, separated by commas. Alternatively use "*" to export all.
TextArray	string array	A text point, which has an array size specified as 1 or more elements . Each element holds an Item or Group name.
format	string	Either "CSV" or "Text" to specify output format. May include suffix '-' followed by: B to exclude break information D to exclude the log date T to exclude the log time M to exclude to log milliseconds
file	integer	Number of file to export where 0 is the latest (active) file, 1 is the previous file etc.
outputfile	string	File name for output file. May include full path, which will be created automatically if it does not exist.

All these arguments are optional, and may be omitted provided there are no further arguments i.e. to specify the 'format', 'datasetname' and 'item list' must be included but 'file' and 'output' may be omitted.

Typical Examples

```
ExportAndViewLog("Balloon", "*")
```

or

```
ExportAndViewLog("Balloon", "Altitude,Fuel,Burning,Lift,Group 1",  
"CSV-BDTM", 0, "output")
```

or

```
ItemList[0] = "Altitude"  
ItemList[1] = "Fuel"  
ItemList[2] = "Burning"  
ItemList[3] = "List"  
ItemList[4] = "Group 1"
```

```
ExportAndViewLog("Balloon", ItemList, "CSV-BDTM", 0, "output")
```

All these commands will export all the data in the specified file, for the named data set to the named output file, in the format specified (as per ExportLog). It then launches an appropriate viewer to display the file, using the Windows file associations.

ExportLog**Syntax**

```
ExportLog ("datasetname", "item list", "format", file, outputfile)
```

or

```
ExportLog ("datasetname", TextArray, "format", file, outputfile)
```

Remarks

Argument	Type	Description
datasetname	string	Name of Data Set to export as text point or constant.
item list	string	List of Items and /or Groups within the data set to export, separated by commas. Alternatively use "*" to export all.
TextArray	string array	A text point, which has an array size specified as 1 or more elements. Each element holds an Item or Group name.
format	string	Either "CSV" or "Text" to specify output format. May include suffix '-' followed by: B to exclude break information D to exclude the log date T to exclude the log time M to exclude to log milliseconds
file	integer	Number of file to export where 0 is the latest (active) file, 1 is the previous file etc.
outputfile	string	File name for output file. May include full path, which will be created automatically if it does not exist.

All these arguments are optional, and may be omitted provided there are no further arguments i.e. to specify the 'format', 'datasetname' and 'item list' must be included but 'file' and 'output' may be omitted.

Typical Examples

```
ExportLog("Balloon", "*")
```

or

```
ExportLog("Balloon", "Altitude,Fuel,Burning,Lift,Group 1" "CSV-BDTM",  
0, "output")
```

or

```
ItemList[0] = "Altitude"  
ItemList[1] = "Fuel"  
ItemList[2] = "Burning"  
ItemList[3] = "List"  
ItemList[4] = "Group 1"
```

```
ExportAndViewLog("Balloon", ItemList, "CSV-BDTM", 0, "output")
```

All these commands will export all the data in the specified file, for the named data set to the named output file, in the format specified.

OpenLogFile

Syntax

```
OpenLogFile("datasetname")
```

or

```
OpenLogFile("databaselink")
```

Remarks

Argument	Type	Description
<i>datasetname</i>	text	Name of Data Set to open as text point or constant.
<i>databaselink</i>	text	Name of Database link to open as text point or constant.

Typical Example

```
OpenLogFile("Balloon")
```

This command will open the log file, ready to start logging. As the function is disk intensive it should not be called frequently.

OpenLogView

Syntax

```
OpenLogView("datasetname", "item list", sessionfile)
```

or

```
OpenLogView("datasetname", TextArray, sessionfile)
```

Remarks

Argument	Type	Description
<i>datasetname</i>	string	Name of Data Set to view as text point or constant.
<i>item list</i>	string	List of Items and/or Groups within the data set to view, separated by commas
<i>TextArray</i>	string array	A text point, which has an array size specified as 1 or more elements. Each element holds an Item or Group name.
<i>sessionfile</i>	string	Optional filename of session information file. The Data Log Viewer is shown with the session settings (e.g. Window position, size, colours, grid options etc. stored in the session file. If omitted, the previous settings are used.

Typical Example

```
OpenLogView("Balloon", "Altitude,Fuel,Burning,Lift,Group 1")
```

or

```
ItemList [0] = "Altitude"
ItemList [1] = "Fuel"
ItemList [2] = "Burning"
ItemList [3] = "Lift"
ItemList [4] = "Group 1"
OpenLogView("Balloon", ItemList)
```

Both these commands will open the Data Log Viewer, and load the Balloon log file, and show the named items.

```
OpenLogView("Balloon", ItemList, "C:\Program Files\Omron\CX-
SUPERVISOR\App\MySessionInfo.txt")
```

This command will open the Data Log Viewer and Balloon log file as above but the Data Log Viewer will always appear in the same position, and with the same settings – not as it was last shown.

StartLogging

Syntax

```
StartLogging("datasetname")
```

or

```
StartLogging("databaselink")
```

Remarks

Argument	Type	Description
<i>datasetname</i>	text	Name of Data Set to start logging as text point or constant.
<i>databaselink</i>	text	Name of Database link to start logging as text point or constant.

Typical Example

```
StartLogging("Process 1")
```

This command will start logging of all items in the named data set. If the file is closed it will be automatically opened.

StopLogging

Syntax

```
StopLogging("datasetname")
```

or

```
StopLogging("databaselink")
```

Remarks

Argument	Type	Description
<i>datasetname</i>	Text	Name of Data Set to stop logging as text point or constant.
<i>databaselink</i>	text	Name of Database link to stop logging as text point or constant.

Typical Example

```
StopLogging("Process 1")
```

This command will stop logging of all items in the named data set.

Database Commands

DBAddNew

Description

Adds a new record to a Recordset. This function will fail if the Recordset is opened with a lock of 'Read Only'.

Syntax

```
returnstate = DBAddNew(level)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This should be a field or recordset level.

Typical Examples

```
Result = DBAddNew("Northwind.Order Details")
```

Using a Recordset connection level, a new record is added with values from all fields associated with a property type 'Add'. Point 'Result' is set true if this was successful.

```
DBAddNew("Northwind.Order Details.OrderID")
```

```
DBAddNew("Northwind.Order Details.ProductID")
```

```
DBAddNew("Northwind.Order Details.Quantity")
```

```
DBAddNew("Northwind.Order Details.UnitPrice")
```

```
DBUpdate("Northwind.Order Details")
```

Using a Field connection level, each required field is added to the new record using multiple calls to DBAddNew(). When the record is complete, it is added by calling the DBUpdate() function

- Note:** To use DBAddNew() with a Recordset level the Recordset must be configured to perform this type of operation i.e it will need to contain fields for any primary keys and 'non null' values required to create a new record. When used at Recordset level all fields associated with the Recordset with property type 'Add' are added (as if calling DBAddNew()) and the record is updated (as if calling DBUpdate()). Points associated with the 'Add' property can be array points, thus enabling you to add multiple records in one operation.
- Note:** When using a Field level connection, the operation may be canceled at any stage before the DBUpdate() function is called by calling the DBExecute() command "CancelUpdate".
- Note:** Only Fields with a property type of 'Value' can be added to a Recordset. The value(s) of the associated points at the time DBUpdate() is called will be used to create the record.

DBCclose

Description

Closes a Connection or Recordset. Closing a Connection will automatically close all recordsets associated with it. Recordsets can be closed in isolation by selecting the appropriate level.

Syntax

```
returnstate = DBCclose(level)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This should be a connection or recordset level.

Typical Examples

```
Result = DBCclose("Northwind.Order Details")
```

Closes the 'Order Details' Recordset

```
Result = DBCclose("Northwind")
```

Closes the connection to the Northwind database, and also any Recordsets which may be open.

DBDelete

Description

Deletes the specified number of records from the current record position. This function works only at the Recordset level. This function will fail if the Recordset is opened with a lock of 'Read Only'.

Syntax

```
returnstate = DBDelete(level, quantity)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This must be a recordset level.
<i>quantity</i>	int	Number of records to delete.

Typical Examples

```
Result = DBDelete("Northwind.Order Details", 10)
```

Delete the next 10 records in the recordset

```
DBMove("First")
```

```
Result = DBDelete("Northwind.Order Details", 10)
```

Delete the first 10 records.

DBExecute

Description

The DBExecute function allows the execution of miscellaneous commands and allows for future expansion by supporting new commands without the need to create more new DB functions.

Syntax

```
return = DBExecute(level, command, parameter)
```

Remarks

Argument	Type	Description
<i>return</i>		1 if the function is successful otherwise 0 except for "Find" and "FindNext" commands which return the record number if found or if not, set the current record to EOF and return -1.
<i>level</i>	text	A text point or constant specifying the connection level, which depends on the command specified.
<i>command</i>	text	Command to execute. May be one of the commands listed below.
<i>parameter</i>	text	Command parameter only required with certain commands. For "Connection", this parameter should hold the new connection string. For "Find" and "FindNext" this parameter should be the search criteria. For "Source" this is the Recordset source. For "Filter" this is the Recordset filter.

Typical Examples

```
Pos = DBExecute("Northwind.Order Details", "Find", "UnitPrice >
14.00")
```

Find the next record satisfying the specified criteria, starting from the current position. Valid search criteria include: "ProductName LIKE 'G'" wildcard search finds all records where ProductName starts with 'G', "Quantity = 5", "Price >= 6.99". Only single search values are allowed, using multiple values with 'AND' or 'OR' will fail.

```
DBExecute("Connection1.Recordset1", "Source", "Table2")
```

Modify the Recordsets source to open a different table than configured.

```
DBExecute("Northwind.Shippers", "Filter", "CompanyName = 'United
Package' ")
```

Apply a filter to display only records with a company name 'United Package'

```
DBExecute("Northwind.Shippers", "Filter", "")
```

Cancel an existing filter (by passing an empty string)

DBExecute Commands

Command	Connection Level	Description
Connection	Connection	Modify the connection string.
BeginTrans	Connection	Begins a new Transaction.
CommitTrans	Connection	Saves any pending changes and ends the current transaction.
RollbackTrans	Connection	Cancels any changes made and ends the transaction.
CommitTransAll	Connection	Saves all changes and ends all transactions.
RollbackTransAll	Connection	Cancels all changes and ends all transactions.
TransCount	Connection	Returns the number of pending transactions.
Requery	Recordset	Re-run the Recordset Query.
CancelUpdate	Recordset	Cancel a DBAddNew operation.
Find	Recordset	Find the specified criteria in a Recordset.
FinNext	Recordset	Combined DBMove("Next"), DBFind() operation.
Source	Recordset	Modify the Recordset source.
Filter	Recordset	Apply a filter to a Recordset.
Save	Recordset	Saves a Recordset in XML format.

DBGetLastError**Description**

Returns the last error string generated by the Database provider, and displays it in a message box.

Syntax

```
returnstate = DBGetLastError(level, display)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	text	The error message from the provider
<i>level</i>	text	A text point or constant specifying the connection level. This must be a Connection level.
<i>display</i>	bool	Optional flag. By default DBGetLastError will display the providers error message in a message box. Setting this flag to FALSE prevents this action.

Typical Examples

```
DBGetLastError("Northwind")
```

or

```
DBGetLastError("Northwind", TRUE)
```

Both the above lines will get and display the last error to occur for the Northwind connection.

```
ErrMsg = DBGetLastError("Northwind", FALSE)
```

The last error to occur for the Northwind connection is stored Text point 'ErrMsg', without displaying a message box.

DBMove

Description

The DBMove function enables you to navigate around a Recordset by moving the position of the 'current record' in the Recordset. When a Recordset is first opened the first record is the current record.

Syntax

```
returnstate = DBMove(level, direction, position)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This must be a Recordset level.
<i>direction</i>	text	A text string indicating where to move to. May be one of: "First" "Last" "Next" "Previous" "Position" "FirstPage" "LastPage" "NextPage" "PreviousPage" "Page" "Bookmark"
<i>position</i>	int/real	This optional parameter is only required when directions of "Position", "Page" and "Bookmark" are used. When used with "Position" and "Page" this parameter must be an integer, and is the record or page number to move to. When used with "Bookmark" this parameter must be a real.

Typical Examples

```
DBMove("Northwind.Order Details", "First")
```

Goto the first record in the Recordset.

```
pos = 3
DBMove("Northwind.Order Details", "Position", pos)
```

Goto the third record in the Recordset.

```
DBMove("Northwind.Order Details", "Page", 6)
```

Goto the sixth page in the Recordset.

Note: Bookmarks are returned from the function 'DBProperty', they enable you to return to a 'marked' record, even after records have been added or deleted

Note: Some Providers do not support moving in the "Previous" direction i.e. cursors are 'Forward-Only'. Some 'Forward-Only' providers do allow moving "First", while some are strictly Forward-Only i.e. the Recordset has to be Re-queried effectively a combined Close then Open operation to reset the cursor back to the start of the Recordset. Some Providers that do support moving "Previous" do not support moving to "Position". However, in order to be consistent, CX-Supervisor ensures that that all operations (except "Bookmarks") will work for any connection to any provider but you need to bear in mind when designing applications that use 'Forward-Only' cursors, that there may be some 'long-winded' acrobatics being performed behind the scenes. See DBSupports() for details of how to check the type of cursor in force.

Note: Bookmarks will only work if specifically supported by the Provider.

DBOpen

Description

Opens a Connection or Recordset. Opening a Connection will automatically open all recordsets associated with it, that are marked as auto open. Recordsets can be opened in isolation by selecting the appropriate level.

Syntax

```
returnstate = DBOpen(level)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This may be a Connection or Recordset level.

Typical Examples

```
DBOpen("Northwind")
```

Open the connection to the Northwind database, and automatically open any Recordsets set to open on connection.

```
done = DBOpen("Northwind.Order Details")
```

Just open a specific Recordset.

DBProperty

Description

Returns the requested property. This function operates on the Recordset and Field levels. The type of the value returned depends on the property requested.

Syntax

```
returnstate = DBProperty(level, property)
```

Remarks

Argument	Type	Description
<i>returnstate</i>		Property value returned. See table for type.
<i>level</i>	text	A text point or constant specifying the connection level. This may be a Recordset or Field level.
<i>property</i>	text	The name of the property to get. For details see the Recordset Properties and Field Properties tables.

Typical Examples

```
Page = DBProperty("CSV.Result", "CurrentPage")
```

Get the current page for the CSV.Result Recordset.

```
FieldSize = DBProperty("Northwind.Customers.Address", "Size")
```

Get the size for the 'Address' field.

Note: The Recordset will only return valid properties when it is Open.

Recordset Properties

The properties of a Recordset are:

Property	Description	Return type
"CurrentRecord"	Current cursor position	Integer
"RecordCount"	Number of records in the Recordset.	Integer
"Bookmark"	Record marker.	Real
"PageCount"	Number of pages in the Recordset.	Integer
"PageSize"	Number of records in a page.	Integer
"CurrentPage"	Page in which the cursor position resides.	Integer
"Source"	Command or SQL that created the Recordset.	Text
"Sort"	Field name(s) the Recordset is sorted on.	Text
"FieldCount"	Number of fields(columns) in the Recordset.	Integer
"BOF"	Current position is at the start of the Recordset.	Bool
"EOF"	Current position is at the end of the Recordset.	Bool

Field Properties

The properties of a Field are

Property	Description	Return type
"Value"	Value of the field at the current position.	As type of field
"Name"	Name of the Field.	String
"Type"	The fields data type.	String
"Size"	Maximum width of the field.	Integer

DBRead

Description

Reads a record from a Recordset to the associated point(s), or if associated points are array points, reads a whole page of records. This function operates on both Recordset and Field levels. At the Field level the associated column values from the Recordsets current position will be copied into the Point (number of elements copied = number of elements in the Point, no paging applies at the Field level).

Syntax

```
returnstate = DBRead(level, reset)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This may be a Recordset or Field level.
<i>reset</i>	bool	This argument is optional and may be omitted. If omitted or TRUE, when the read is complete the record cursor is reset to the position prior to reading.

Typical Examples

```
DBRead("Northwind.Customers")
```

Read the next page of records from the 'Customers' Recordset.

```
DBRead("Northwind.Customers", FALSE)
```

Read the next page of records from the 'Customers' Recordset, and leave the cursor at the next record.

```
DBRead("Northwind.Customers.Address")
```

The Address field is read. If it is an array point, the Address is read from subsequent records until the array has been filled.

Note: Use with `reset = TRUE` is useful if the read operation is being combined with a subsequent Write operation i.e. you can read in a set of records - resetting the cursor, make modifications to some of the fields and then Write the changes back to the Recordset.

Note: Use with `reset = FALSE` will leave the current position at the start of the next set of records. This option can be of benefit if the Provider only supports forward moving cursors, or you simply want to step through the records a page at a time.

DBSchema**Description**

Issues commands to read schema results or properties or set up new schema criteria. This function operates only at a Schema level.

Syntax

```
return = DBSchema(level, command, parameters...)
```

Remarks

Argument	Type	Description
<i>return</i>		Value returned by command. For some commands e.g. "RecordCount" this is an integer value, for other commands this is a text value.
<i>level</i>	text	A text point or constant specifying the connection level. This must be a Schema level.
<i>command</i>	text	The command must be one of the following: "Read" - Transfers a schema page into the associated point "Set" - Enables schema details to be modified "Type" - Returns the current Schema Type "Criteria" - Returns the current Schema Criteria "Filter" - Returns the current Schema Filter "RecordCount" - Returns the number of records in the current Schema "PageCount" - Returns the number of pages in the current Schema "CurrentPage" - Returns the current Schema page
<i>parameters</i>		Some commands require 1 or more extra parameters. "Read" takes an optional parameter 'Page Number' of type integer. If no 'Page Number' is supplied, this function will return page 1 when first called and automatically return the next page of schemas for each subsequent call, cycling back to the beginning when all pages have been returned. "Set" takes three text parameters for Schema 'Name', 'Criteria' and 'Filter'.

Typical Examples

```
NumberOfRecords = DBSchema("Invoice.Data Types", "RecordCount")
```

Read the Number of records in the Schema.

```
DBSchema("Invoice.Data types", "Read", 2)
```

Read Schema page 2 results into the associated point.

```
DBSchema("Invoice.Data Types", "Set", "Columns", "COLUMN_NAME", "")
```

Set a new Schema to return column names.

DBState**Description**

Reports if the specified level is in the requested state.

Syntax

```
return = DBState(level, state)
```

Remarks

Argument	Type	Description
<i>return</i>	bool	1 if the specified level is in the requested state, otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This may be a Connection or Recordset level.
<i>state</i>	text	The requested state must be either "Open" or "Closed"

Typical Examples

```
State = DBState("Invoice", "Closed")
```

Checks if the Connection "Invoice" is currently closed.

```
State = DBState("Northwind.Customers", "Open")
```

Checks if the Recordset "Customers" is currently open.

DBSupports**Description**

Returns TRUE if the specified Recordset supports the requested operation.

Syntax

```
return = DBState(level, operation)
```

Remarks

Argument	Type	Description
<i>return</i>	bool	1 if the specified Recordset supports the requested operation, otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This must be a Recordset level.
<i>operation</i>	text	The requested operation may be one of: "AddNew", "Bookmark", "Delete", "Find", "MovePrevious" or "Update"

Typical Example

```
Result = DBSupports("CSV.Recordset1", "Delete")
```

Checks if records can be deleted in 'Recordset1'

Note: If the "MovePrevious" operation is not supported then only 'Forward-Only' cursor movements are supported.

DBUpdate**Description**

Update the record being added in a Recordset. Used in conjunction with DBAddNew to commit a new record.

Syntax

```
returnstate = DBUpdate(level)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0
<i>level</i>	text	A text point or constant specifying the connection level. This must be a Recordset level.

Typical Example

```
DBAddNew("Northwind.Order Details.OrderID")
DBAddNew("Northwind.Order Details.ProductID")
DBAddNew("Northwind.Order Details.Quantity")
DBAddNew("Northwind.Order Details.UnitPrice")
DBUpdate("Northwind.Order Details")
```

Each field is added to the new record using multiple calls to DBAddNew(). When the record is complete, it is added to the Recordset by calling the DBUpdate() function.

DBWrite**Description**

Writes a set of records into a Recordset from the associated point(s). This function operates on both Recordset and Field levels. At the Recordset level all the associated points values from the Points will be written into the Recordset starting at the current record (1 page of values will be written for each Point). At the Field level the associated values from the point are written into the Recordsets starting at the current position. The number of elements written = number of elements in the Point. This function will fail, if the Recordset is opened with a Lock of 'Read Only'.

Syntax

```
return = DBWrite(level, reset)
```

Remarks

Argument	Type	Description
<i>return</i>	Bool	1 if the function is successful otherwise 0
<i>level</i>	Text	A text point or constant specifying the connection level. This must be a Recordset level.
<i>reset</i>	Bool	This argument is optional and may be omitted. If omitted or TRUE, when the write is complete the record cursor is reset to the position prior to writing.

Typical Examples

```
DBWrite("Northwind.Customers")
```

Write all point values to the associated Customers fields.

```
DBWrite("Northwind.Customers.Address", FALSE)
```

Write the point values to the Address column, and leave the cursor at the next set of records.

Serial Port Functions

InputCOMPort

Description

Sets the serial communications port for receiving ASCII text messages. Any message received is placed in the text point. The boolean flag is set true to indicate that a message has been received. It is up to the user to reset this flag between receiving messages in order to indicate that a new message is present.

Syntax

```
ReturnState = InputCOMPort(PortNumber, Message, MessagePresent)
```

Remarks

Argument	Type	Description
<i>ReturnState</i>	Bool	True if successful else false.
<i>PortNumber</i>	Integer	The number of the port previously configured using the function SetupCOMPort and opened with OpenCOMPort.
<i>message</i>	Text	Text point to hold ASCII text message received through the port.
<i>MessagePresent</i>	Bool	Boolean point indicating that a message has been received.

Typical Example:

```
bState = InputCOMPort(1, Msg, bTransmission)
```

OutputCOMPort

Description

Sends an ASCII text message out through the designated serial communications port.

Syntax

```
ReturnState = OutputCOMPort(PortNumber, Message)
```

Remarks

Argument	Type	Description
<i>ReturnState</i>	Bool	True if successful else false.
<i>PortNumber</i>	Integer	The number of the port previously configured using the function SetupCOMPort and opened with OpenCOMPort.
<i>message</i>	Text	Text point holding the ASCII text message to send through the port.

Typical Example:

```
bState = OutputCOMPort(1, Msg)
```

CloseCOMPort

Description

Closes the designated serial communications port on the PC. The port must have been configured and opened before it can be closed.

Syntax

```
ReturnState = CloseCOMPort(PortNumber)
```

Remarks

Argument	Type	Description
<i>ReturnState</i>	Bool	True if successful else false.
<i>PortNumber</i>	Integer	The number of the port previously configured using the function SetupCOMPort and opened using the script function OpenCOMPort.

Typical Example:

```
bState = CloseCOMPort(1)
```

OpenCOMPort

Description

Opens the designated serial communications port on the PC for transmitting or receiving data. The port must have been configured before it can be opened.

Syntax

```
ReturnState = OpenCOMPort(PortNumber)
```

Remarks

Argument	Type	Description
<i>ReturnState</i>	Bool	True if successful else false.
<i>portNumber</i>	Integer	The number of the port previously configured using the function SetupCOMPort.

Typical Example:

```
bState = OpenCOMPort(1)
```

SetupCOMPort

Description

Configures the designated serial communications port on the PC for transmitting or receiving data.

Syntax

```
ReturnState = SetupCOMPort(PortNumber, ConfigurationString,  
HandShaking, TerminationChar, ControlCharFlag)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	Bool	True if successful else false.
<i>portnumber</i>	Integer	The number of the serial port to be configured.
ConfigurationString	Text	A string indicating the desired Baud rate, Parity, number of data bits and stop bits.
HandShaking	Integer	The required handshaking protocol. Valid values are 0 – None 1 - XonXoff 2 – RTS 3 - RTS & XonXoff
TerminationChar	Integer	A character indicating the end of the message.
ControlCharFlag	Bool	A flag indicating that control characters contained in a received message should be Ignored.

Typical Example:

```
bState = SetupCOMPort(2, "9600,N,8,1", 0, 0x0D, TRUE)
```

ActiveX Functions

GetProperty

Description

Gets the value of a property of an OLE object and stores it in a point.

Syntax

```
propertyvalue = GetProperty(object, property, ...)
```

Remarks

Argument	Type	Description
<i>propertyvalue</i>	n/a	The value of the property. Type is dependant on the type of the property.
<i>object</i>	Text	The name of the OLE object to get the property of.
<i>property</i>	Text	The name of the property to get.
...	n/a	Any number of parameters for the property.

Typical Examples

```
OLE1Height = GetProperty("OLE1", "Height")
```

This will read the property 'Height' from the OLE object 'OLE1' and store it in the point 'OLEHeight'.

```
DM100Value = GetProperty("CXComms1", "DM", 100)
```

This will read the property 'DM' (with one parameter 100) from the OLE object 'CXComms1' and store it in the point 'DM100Value'.

PutProperty

Description

Puts a value stored in a point into the property of an OLE object.

Syntax

```
PutProperty(object, property, ..., value)
```

Remarks

Argument	Type	Description
<i>object</i>	Text	The name of the OLE object containing the property to change.
<i>property</i>	Text	The name of the property to put.
<i>...</i>	n/a	Any number of parameters for the property.
<i>value</i>	n/a	The value to write to the property. Type is dependant on the type of property. Can also be a number.

Typical Examples

```
PutProperty("OLE1", "Left", NewLeftValue)
```

This will write the value stored in the point NewLeftValue to the property 'Left' in the OLE object 'OLE1'.

```
PutProperty("CXComms1", "DM" 10, NewValue)
```

This will write the value stored in the point NewValue to the property 'DM' (with one parameter 10) in the OLE object 'CXComms1'.

```
PutProperty("Gauge1", "Value", 25.2)
```

This will write the value 25.2 to the object 'Gauge1'.

Execute**Description**

Execute a method of an OLE object.

Syntax

```
Execute(object, method, ...)
```

Remarks

Argument	Type	Description
<i>object</i>	Text	The name of the OLE object.
<i>method</i>	Text	The name of the method to execute.
<i>...</i>	n/a	Any number of parameters for the method.

Typical Examples

```
Execute("OLE1", "Start")
```

This will call the method 'Start' on the object 'OLE1'.

```
Execute("CXComms1", "OpenPLC", "MyPLC")
```

This will call the method 'OpenPLC' with one text parameter 'MyPLC' on the OLE object 'CXComms1'

ExecuteVBScript

Description

Creates aliases allowing Visual Basic Script to be executed in line. This uses the Windows Scripting Host. See Appendix C for a list of supported functions and details of the Windows Scripting Host.

Syntax

```
@VBSCRIPT  
@ENDSCRIPT
```

Typical Examples

```
@VBSCRIPT  
OLE1.LEFT = Point("PointName")  
@ENDSCRIPT
```

This Visual Basic Script will write the value from the point 'PointName' into the property 'Left' of the OLE object 'OLE1'.

ExecuteJScript

Description

Creates aliases allowing Java Script to be executed in line. See Appendix D for a list of supported functions and details of the Windows Scripting Host.

Syntax

```
@JSCRIPT  
@ENDSCRIPT
```

Typical Examples

```
@JSCRIPT  
Point("PointName") = OLE_1.Height;  
@ENDSCRIPT
```

This Java Script will write the value of the property 'Height' from the OLE object 'OLE1' into the Point named 'PointName'.

Note: The Java Script can not include the { or } characters. To use these, put the script in a text file and use the ExecuteJScriptFile function.

ExecuteVBScriptFile

Description

Allows Visual Basic script stored in a text file to be executed. This uses the windows scripting host which must be installed. See Appendix C for a list of supported functions.

Syntax

```
returnstate = ExecuteVBScriptFile(scriptfile)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0.
<i>scriptfile</i>	Text	The name of the file with the Visual Basic Script to execute.

Typical Examples

```
returnstate = ExecuteVBScriptFile("c:\vbscript.txt")
```

This will execute the Visual Basic Script stored in "c:\vbscript.txt".

ExecuteJScriptFile**Description**

Allows Java script stored in a text file to be executed. This uses the windows scripting host which must be installed. See Appendix D for a list of supported functions.

Syntax

```
returnstate = ExecuteJScriptFile(scriptfile)
```

Remarks

Argument	Type	Description
<i>returnstate</i>	bool	1 if the function is successful otherwise 0.
<i>scriptfile</i>	Text	The name of the file with the Java Script to execute.

Typical Examples

```
returnstate = ExecuteJScriptFile("c:\jscript.txt")
```

This will execute the Java Script stored in "c:\jscript.txt".

Punctuation**Command String Delimiters****Syntax**

```
DDEExecute(channel, {[command1][command2][command3]})
```

Typical Example

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
DDEExecute(channelname, {[OPEN("C:\EXCEL\WORK\SHEET2.XLS")]} )
```

It is possible to pass multiple commands in one DDEExecute() command. Each command is surrounded by square brackets [...]. There must be no space between the closure of one square bracket and the opening of the next [...][...].

The '{' and '}' braces must be inserted around the whole set of commands {[...][...]} or an error is reported. The braces act as delimiters for the whole command string. This allows the actual commands in the command string to contain quotes.

Indentation**Typical Examples**

```
IF burner AND fuel > 0 AND rate > 0 THEN
  lift = lift + rate/5
ELSE
  IF altitude > 140 THEN
    lift = lift - 0.2
  ENDIF
ENDIF

IF burner AND fuel > 0 AND rate > 0 THEN
  lift = lift + rate/5
ELSE
  IF altitude > 140 THEN
    lift = lift - 0.2
  ENDIF
ENDIF
```

Both examples provide identical functionality, but the use of indentation, either spaces or tabs to show the construction of the statements aids readability.

The use of the ELSEIF statement in this example was omitted for clarity.

Multiple Commands**Typical Examples**

```
count = 75
result = log(count)

count = 75 : result = log(count)
```

Both examples provide identical functionality, but the use of the colon between statements allows both to reside on the same line.

Parenthesis

Typical Examples

```
result = 20 + 30 * 40
```

The result is 1220.

```
result = (20 + 30) * 40
```

The values in parenthesis are calculated first. The result is 2000.

References

Refer to chapter 4, Arithmetic Operations for further details.

Quotation Marks

Typical Examples

```
name = "Valve position"
```

The Text point 'name' is assigned associated text, contained within quotation marks. Quotation marks must be used in this instance.

```
channelname = DDEInitiate("Excel", "Sheet1.xls")
```

The Integer point 'channelname' is provided with a DDE link to an application which is run by an executable filename, and to the associated application file. Quotation marks must be used for server names, topic names, DDE commands and item names.

```
BlueCarsAck = IsAlarmAcknowledged("BLUEPAINT")
```

The point 'BlueCarsAck' is assigned a Boolean state based on the alarm 'BLUEPAINT'. Quotation marks must be used for an alarm name.

Remarks

Syntax

```
REM | rem comment
```

or

```
`comment
```

Remarks

Argument	Type	Description
<i>Comment</i>	---	Descriptive text.

Typical Examples

```
REM The following statement adds two numbers
```

```
result = 45 + 754
```

```
result = 45 + 754 `add two numbers
```

Indirection within Script Commands and Expressions

It is possible to use text points directly or indirectly in place of literal string arguments within scripts and expressions. For instance, each of the following commands has the same effect:

- ◆ Using a string literal;

```
PlayOLE("ole_1", 0)
```
- ◆ Using a textpoint directly;

```
textpoint = "ole_1"  
PlayOLE(textpoint, 0)
```
- ◆ Using a textpoint indirectly via the '^' notation.

```
text = "ole_1"  
textpoint = "text"  
PlayOLE(^textpoint, 0)
```

It is possible to use text points indirectly in place of point name arguments within script commands. For instance, each of the following commands has the same effect:

- ◆ Using a point name directly;

```
verbnumber = 0  
PlayOLE("ole_1", verbnumber)
```
- ◆ Using a textpoint indirectly via the '^' notation.

```
verbnumber = 0  
textpoint = "verbnumber"  
PlayOLE("ole_1", ^textpoint)
```

An example using Indirection

The value of point indirection can be seen in a situation where it is necessary to dynamically change the pointname that an object is linked to. In the following example a toggle button is configured to control the Boolean state of one of four points:

- ◆ The four Boolean points to be controlled are called 'motor1', 'motor2', 'motor3' and 'motor4'.
- ◆ The text point 'textpoint' is used to store the name of the Boolean point to be controlled.
- ◆ The text point 'text' is used to store the string value of the integer point 'index'
- ◆ The integer point 'index' (which has a range 1-4) is used to dynamically change the point being controlled.
- ◆ Access to any of the four Boolean points 'motor1', 'motor2', 'motor3', 'motor4' can be achieved by applying indirection to 'textpoint' using the '^' notation and changing the contents of 'textpoint'.

For instance, in order to dynamically change the Boolean point a toggle button is linked to follow these steps.

- 1, 2, 3...** 1. Link the toggle button to a textpoint using indirection e.g. ^textpoint.

2. Link the following script code to run as required. e.g. on clicking a button.
 - `Text = ValueToText(index)`
 - `TextPoint = "motor" + text`
3. The `ValueToText` function converts the integer value of the point 'index' into a string held in the textpoint 'text'. Therefore the point 'text' contains either '1', '2', '3' or '4'. The expression 'motor' + text appends the contents of the point 'text' to the literal string 'motor'. Therefore 'textpoint' contains either 'motor1', 'motor2', 'motor3' or 'motor4' dependant on the value of 'index'. Change the value of the 'index' to determine which Boolean point to control. e.g. via the Edit Point Value (Analogue) animation.

Point Arrays within Script Commands and Expressions

It is possible to access the elements of a point array directly or indirectly from within scripts or expressions.

- ◆ Setting the value of an array point directly;
`arraypoint[2] = 30`
- ◆ Getting the value of an array point directly;
`value = arraypoint[2]`
- ◆ Setting the value of an array point using indirection;
`textpoint = "arraypoint"`
`^textpoint[2] = 30`
- ◆ Getting the value of an array point using indirection;
`textpoint = "arraypoint"`
`value = ^textpoint[2]`
- ◆ Setting the value of an array point using `SetPointValue()`;
`SetPointValue(arraypoint, 2, 30)`
- ◆ Getting the value of an array point using `GetPointValue()`.
`value = GetPointValue(arraypoint, 2)`

An example using Point Arrays

The value of array points can be seen in a situation where it is necessary to dynamically change the pointname that an object is linked to. In the following example a toggle button is configured to control the Boolean state of one of four elements of an array point.

The Boolean array point 'motor' is configured to contain 4 elements.

The integer point 'index' (which has a range 0-3) is used to dynamically change the element of the point being controlled.

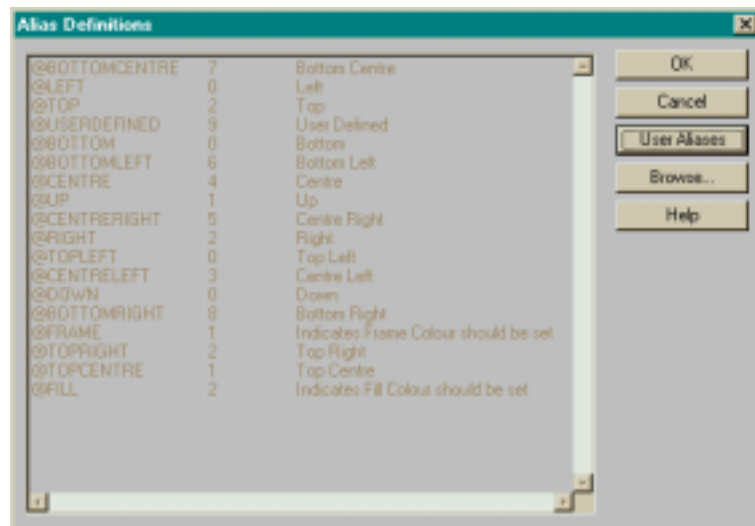

In order to dynamically change the element of a Boolean point that a toggle button is linked to follow these steps.

- 1, 2, 3... 1. Link the toggle button to an array point. e.g. 'motor[index]'.
2. Change the value of the 'index' to determine which element of the Boolean point to control. e.g. via the Edit Point Value (Analogue) animation.

Using Aliases

This facility is used to declare an alias - that is, to define a text string that can be used in place of another text string or a number within any script or expression. The Alias Definitions dialog is displayed by selecting the "Alias Definition..." option from the Project menu. It can also be displayed if "Aliases..." is selected from the script editor. The dialog displays either the User defined aliases or the preset System aliases and is toggled between these two displays by pressing the User/System Alias button.

The following illustration shows the Alias Definitions dialog displaying a number of User defined aliases. The System aliases are pre-defined and can not be edited or added to.

Syntax:

@AliasName Alias definition 'optional comment

Remarks:

Argument	Type	Description
@AliasName	string	The string name of the alias
Alias definition	string	This is a string representing the actual text or expression of the expanded alias.
'comment	string	This is an optional comment.

The @ symbol at the beginning of each line initiates each alias command. For example, the text string @SomePoint could be used to represent any sequence of characters in a script or expression – e.g. it could be defined as:

```
@SomePoint = InArray[1]
```

or even

```
@SomePoint = InArray[1] + InArray[2] / 2
```

This is an easy way of identifying the individual members of array points. It can also be used to associate names with numbers, for example,

```
@SecondsPerDay = 86400
```

Alias definitions are stored in a simple text file in the project directory, called <project name>.pre. The format of the file consists of any number of lines such as:

```
@Test1 = InArray[12] * 10
```

i.e. an @ symbol followed by the name of the alias, then an equals sign (or space), followed by the definition of the alias. Anything that follows the last apostrophe (') symbol on a line is interpreted as a comment. Any line which does not start with the @ symbol is also assumed to be a comment.

Typical Examples

```
Declare boiler temperatures
@BoilerTemp1 = InArray[0] ' for boiler room 1
@BoilerTemp2 = InArray[1] ' for boiler room 2
@SecondsPerMinute = 60 ' sets duration
```

Aliases may also be used to create a complicated expression such as

```
@HYPOTENUSE sqrt(Opposite * Opposite + Adjacent * Adjacent)
'Calculates length of Hypotenuse
```

This can be used in a script in the following way:

```
Opposite = 8.45
Adjacent = 9.756
length = @HYPOTENUSE
```

where Opposite, Adjacent and length are all REAL points.

Note: Changing an alias definition after it has been used in an expression or script will not automatically change the result in the script. The appropriate script or expression where that alias is used must be accessed and recompiled by pressing the OK button in order to apply the changes.

CHAPTER 5

Script Examples

This chapter provides two applications for a script. The first script is a typical script exercising the basic commands. The second script is specific for DDE use. Both examples are described twice, once as a whole, and once on a line by line basis.

Balloon Script

The following script applies to a simple game.

The user must attempt to land the balloon on the plateau on the right, using the **Max/Min** slider control throughout the flight. Clicking **Reset** clears the current game and initialises a new game. Clicking the **on/off** pushbutton starts the game.

When the balloon is airborne, clouds move slowly horizontally and change colour slightly. Clicking **Help** at any time brings up a special help page; clicking **Close** from this help page returns the user to the game. The blue gauge shows the amount of fuel consumed and left.

The project consists of three page scripts and one object. The three page scripts are initiated at varied intervals: 10 milliseconds, 100 milliseconds and 1000 milliseconds.

The page script initiated at intervals of 10 milliseconds determines the position of each cloud, and the speed at which each cloud moves. The page script initiated at intervals of 1000 milliseconds determines how the balloon reacts to the conditions.

The page script initiated at intervals of 100 milliseconds provides the main configuration of the game, reacting to user input and moving the balloon accordingly. This page script is as follows:

```
IF burner AND alt > 400.0 THEN
  burner = FALSE
ENDIF
IF burner THEN
  fuel = fuel - rate
  IF fuel < 0.0 THEN
    fuel = 0.0
    burner = FALSE
  ENDIF
ENDIF

IF burner AND fuel > 0.0 AND rate > 0.0 THEN
  lift = lift + rate/5.0
ELSE
  IF alt > 140.0 THEN
    lift = lift - 0.2
  ENDIF
ENDIF
IF lift < -10.0 THEN
  lift = -10.0
ENDIF
alt = alt + lift
IF alt <= 140.0 THEN
  IF distance>630.0 AND distance<660.0 AND lift>=-3.0 THEN
    winner = TRUE
    burner = FALSE
  ENDIF
  IF lift < -3.0 then
    crash = TRUE
    burner = FALSE
  ENDIF
  lift = 0.0
ENDIF

speed = (alt-140.0 )/100.0
IF speed < 0.0 then
  speed = 0.0
ENDIF

distance = distance + speed
```

The following paragraphs describe the above script on a line by line basis.

```
IF burner AND alt > 400.0 THEN
  burner = FALSE
ENDIF
```

If the fuel burner is on, based on Boolean point 'burner' set to 'TRUE', and the altitude of the balloon, based on point 'alt', exceeds 400, then the fuel burner is turned off. Point 'alt' is measured in pixels between 140 and 1000, so the value of 400 is the height in pixels.

```
IF burner THEN
  fuel = fuel - rate
  IF fuel < 0.0 THEN
    fuel = 0.0
    burner = FALSE
  ENDIF
ENDIF
```

If the fuel burner is on, the amount of fuel remaining decreases by the rate of ascent. The rate of ascent, point 'rate' can be modified by moving the slider. If point 'fuel' currently has a value of less than 0, then there is no fuel left and the fuel burner is turned off.

```
IF burner AND fuel > 0.0 AND rate > 0.0 THEN
  lift = lift + rate/5.0
ELSE
  IF alt > 140.0 THEN
    lift = lift - 0.2
  ENDIF
ENDIF
```

If the fuel burner is on, and there is still fuel left, and the rate of ascent exceeds 0 (the balloon has taken off) then point 'lift' is incremented by the rate of ascent divided by 5 to allow the balloon to climb. Otherwise the balloon must be descending and point 'lift' is decremented by 0.2.

```
IF lift < -10.0 THEN
  lift = -10.0
ENDIF
```

Once point 'lift' reaches -10, it is not allowed to go lower.

```
alt = alt + lift
```

The altitude of the balloon is incremented by point 'lift'.

```
IF alt <= 140.0 THEN
  IF distance>630.0 AND distance<660.0 AND lift>=-3.0 THEN
    winner = TRUE
    burner = FALSE
  ENDIF
```

If the balloon has hit the ground (point 'alt' equals 140), then provided it is on the plateau (the position of the balloon in pixels defined by point 'distance' is between 630 and 660) and the rate of descent is not too fast (defined by point 'lift'), then the game is won.

```
IF lift < -3.0 then
  crash = TRUE
  burner = FALSE
ENDIF
```

If the balloon has hit the ground (point 'alt' equals 140), then if the rate of descent is not too fast (defined by point 'lift'), then the game is lost.

```
lift = 0.0
ENDIF
```

Point 'lift' is reset.

```
speed = (alt-140.0 )/100.0
IF speed < 0.0 then
  speed = 0.0
ENDIF
```

Point 'speed' is calculated based on the altitude.

```
distance = distance + speed
```

Point 'distance' is calculated based on the speed.

DDE Script

The following script demonstrates how to generate a report using Microsoft Word for Windows application. It is a more detailed example targeted at more proficient script writers. The example assumes the following:

A file 'REPORT.DOC' exists in a directory named "C:\WINWORD\WORK".

A text point 'Header' exists with the default text "CX-Supervisor Report — Date.

A real point named 'Input' exists with a default value of '325.99'. DDE Access of at least Read/Only is required for the point.

A real point named 'Output' exists with a default value of '250.00'. DDE Access of at least Read/Only is required for the point.

```
'Establish a connection to the report document
channel = DDEInitiate("Winword", "C:\WINWORD\WORK\REPORT.DOC")

IF channel > 0 THEN
  'Output header and date
  DDEPoke(channel, "\StartOfDoc", Header)
  DDEPoke(channel, "\EndOfDoc", $Date)
  DDEExecute(channel, {[EndOfDocument]})
  DDEExecute(channel, {[InsertPara]})
  DDEExecute(channel, {[InsertPara]})

  'Output column headings (note : Chr$(9) is a TAB)
  DDEExecute(channel, {[Insert "Time" + Chr$(9) + "Input"
    + Chr$(9) + "Output"]})
  DDEExecute(channel, {[InsertPara]})

  'Change header and column headings to Bold font
  DDEExecute(channel, {[EditSelectAll]})
  DDEExecute(channel, {[FormatFont .Bold = 1, .Underline
    = 0]})
  DDEExecute(channel, {[EndOfDocument]})

  'Change font to normal for the data fields
```

```

DDEExecute(channel, {[SelectCurWord]})
DDEExecute(channel, {[FormatFont .Bold = 0]})
DDEExecute(channel, {[EndOfDocument]})

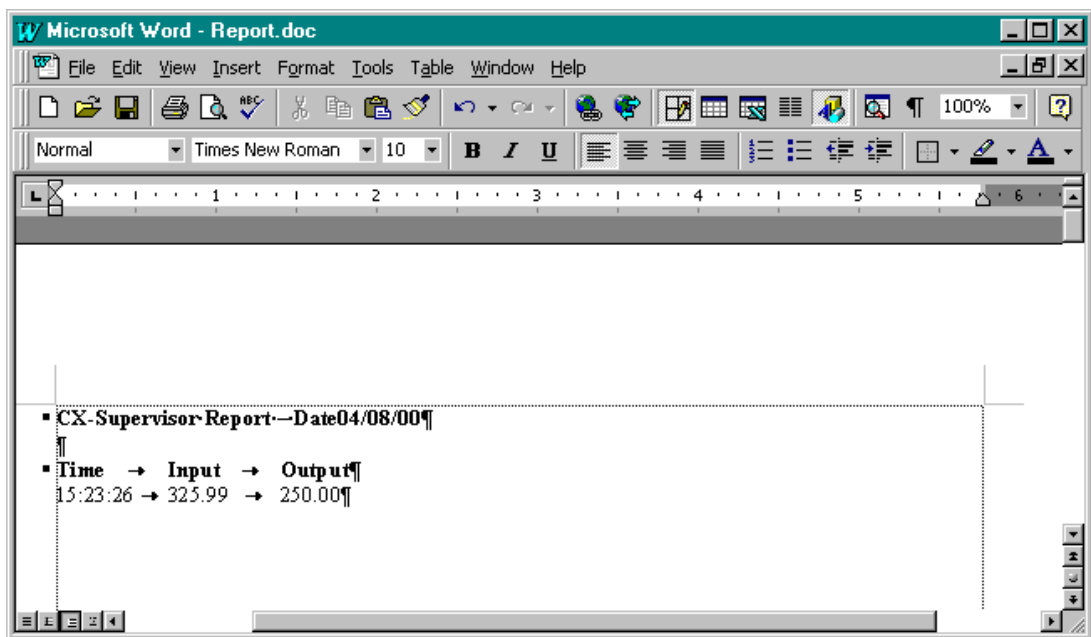

'Output the data fields
DDEPoke(channel, "\EndOfDoc", $Time)
DDEExecute(channel, {[EndOfDocument]})

DDEExecute(channel, {[Insert Chr$(9)]})
DDEPoke(channel, "\EndOfDoc", Input)
DDEExecute(channel, {[EndOfDocument]})

DDEExecute(channel, {[Insert Chr$(9)]})
DDEPoke(channel, "\EndOfDoc", Output)
ENDIF

```

The script will generate the following output in 'REPORT.DOC':

The following paragraphs describe the above script on a line by line basis. The description assumes the reader has a knowledge of the target application, in this instance Microsoft Word for Windows.

'Establish a connection to the report document

A remark describing the next few lines of code.

```
channel = DDEInitiate("Winword", "C:\WINWORD\WORK\REPORT.DOC")
```

The point 'channel' is assigned with the Microsoft Word for Windows executable file filename (minus the file extension) 'Winword', and the path and filename of the topic, 'REPORT.DOC'.

```
IF channel > 0 THEN
```

The point 'channel' is tested to ensure it is not empty, and therefore the demonstration continues to run.

```
  `Output header and date
  DDEPoke(channel, "\StartOfDoc", Header)
```

Microsoft Word for Windows is passed a navigational 'go to start of document' command, with the text contained within point 'Header'.

```
  DDEPoke(channel, "\EndOfDoc", $Date)
```

Microsoft Word for Windows is passed a navigational 'go to end of document' command, and the date contained within system point '\$Date' is inserted.

```
  DDEExecute(channel, {[EndOfDocument]})
  DDEExecute(channel, {[InsertPara]})
  DDEExecute(channel, {[InsertPara]})
```

Microsoft Word for Windows is passed an EndOfDocument command, followed by two InsertPara commands.

```
  `Output column headings (note : Chr$(9) is a TAB)
  DDEExecute(channel, {[Insert "Time" + Chr$(9) + "Input"
    + Chr$(9) + "Output"]})
  DDEExecute(channel, {[InsertPara]})
```

Microsoft Word for Windows is passed an Insert command, containing 'Time' followed by a tab character, followed by 'Input', followed by a tab character, followed by 'Output', followed by an InsertPara command.

```
  `Change header and column headings to Bold font
  DDEExecute(channel, {[EditSelectAll]})
  DDEExecute(channel, {[FormatFont .Bold = 1, .Underline = 0]})
  DDEExecute(channel, {[EndOfDocument]})
```

Microsoft Word for Windows is passed an EditSelectAll command supplying an extended selection across all of 'REPORT.DOC'. The selected area is reformatted as emboldened, with no underline (both .Bold and .Underline are Boolean with an 'on' and 'off' state).

```
  `Change font to normal for the data fields
  DDEExecute(channel, {[SelectCurWord]})
  DDEExecute(channel, {[FormatFont .Bold = 0]})
  DDEExecute(channel, {[EndOfDocument]})
```

Microsoft Word for Windows is passed an SelectCurWord command supplying an extended selection across the current word. The selected area is reformatted as normal (.Bold is Boolean with an 'ON' and 'OFF' state). An EndOfDocument command is also passed.

```
  `Output the data fields
  DDEPoke(channel, "\EndOfDoc", $Time)
  DDEExecute(channel, {[EndOfDocument]})
```

Microsoft Word for Windows is passed a navigational 'go to end of document' command, and the time contained within system point '\$Time' is inserted. An EndOfDocument command is also passed.

```
DDEExecute(channel, {[Insert Chr$(9)])}
DDEPoke(channel, "\EndOfDoc", Input)
DDEExecute(channel, {[EndOfDocument]})
```

Microsoft Word for Windows is passed an Insert command, containing a tab character, followed by a navigational 'go to end of document' command, followed by the value of point 'Input', followed by an EndOfDocument command.

```
DDEExecute(channel, {[Insert Chr$(9)]})
DDEPoke(channel, "\EndOfDoc", Output)
```

Microsoft Word for Windows is passed an Insert command, containing a tab character, followed by a navigational 'go to end of document' command, followed by the value of point 'Output', followed by an EndOfDocument command.

```
ENDIF
```

If point 'channel' is empty, the lines of script within the IF THEN ENDIF control statement are ignored.

The page script is finished.

CHAPTER 6

Colour Palette

This chapter discusses the colour palette. A colour may be specified by its name or number. The following table provides a cross-reference between these. Some colour names made up of more than one word are separated by an underscore or a hyphen. A specified colour can be changed in the CX-Supervisor development environment for the current session; such changes cannot be saved to a Page or Project, unless colours are changed from the Colour Palette located under the *General Settings* submenu in the *Project* menu.

Using a 16 colour-based screen resolution (consult the Microsoft Windows documentation for further information) colours 16 to 65 are dithered from the sixteen base colours. Higher colour-based resolutions are not dithered.

No.	Colour	No.	Colour
0	black	12	purple
1	blue	13	olive
2	green	14	dark_grey
3	cyan	15	light-grey
4	red	16	pale-green
5	magenta	17	light-blue
6	yellow	18	off-white
7	white	19	grey
8	dark_blue	20	cherry
9	dark_green	21	silver
10	blue-green	22	apple
11	brown	23	orange
		24-65	Not used

Appendix A

OPC Communications Control

This appendix contains a list of the available component properties and gives details of the Visual Basic script interface. These properties can be set in run time by using a Visual Basic script command – for example: -

```
OMRONCXOPCCommunicationsControl1.ServerNodeName = "\\NAME"
```

The Script Interface defines the Visual Basic script interface for the OPC communications control. See ExecuteVBScript script functions for more information on running Visual Basic Script.

Component Properties

Property Title	Example	Description
DisplayErrors	True False	When set True, the object will display a message box for any errors. If set to False, error messages are not displayed.
ProjectName		Name of .OPC file containing the client setup.
ServerComputerName	"MyPC"	This is the name of the PC with the OPC Server.
ServerName		Name of the OPC Server to connect to. e.g. OMRON.OpenDataServer.1
ServerProjectName		Optional filename, which if specified causes the OPC Server to use the specified file, if supported by the server.

Script Interface

The Script Interface defines the methods for the OPC communications control.

Functions

Value	Function for getting and setting an OPC item value.
Read	Function to read the value of an OPC item.
Write	Function to write the value of an OPC item.

Value

Reads or writes the value of an OPC item.

Example 1 – Reading a value:

```
intVal = OMRONCXOPCCommunicationsControl1.Value("MyGroup", "BoilerTemp")
```

In this example, the OPC item 'BoilerTemp' in the OPC group called "MyGroup" will be read from the OPC Server and will be stored in 'intVal'.

Example 2 – Writing a value:

```
OMRONCXOPCCommunicationsControl1.Value("MyGroup", "BoilerTemp") = 50
```

In this example, the value 50 will be written to the OPC item 'BoilerTemp'.

Note: 'Value' is the default property so is assumed if omitted. Therefore, the following examples are the same:

```
intVal = OMRONCXOPCCommunicationsControl1.Value("MyGroup", "BoilerTemp")  
and  
intVal = OMRONCXOPCCommunicationsControl1 ("MyGroup", "BoilerTemp")
```

Read

Reads the value of an OPC item.

Example of synchronous read:

```
intVal = OMRONCXOPCCommunicationsControl1.Read("MyGroup", "BoilerTemp")
```

In this example, the OPC item 'BoilerTemp' in the OPC group called "MyGroup" will be read from the OPC Server and will be stored in 'intVal'. The script will wait for the read operation to complete before continuing to execute the next line. This is identical to the operation of the 'Value' method.

Write

Writes the value of an OPC item.

Example of synchronous write:

```
OMRONCXOPCCommunicationsControl1.Write "MyGroup", "BoilerTemp", NewValue
```

In this example, 'NewValue' will be written to the OPC item 'BoilerTemp' in the OPC group called "MyGroup". The script will wait for the write operation to complete before continuing to execute the next line. This is identical to the operation of the 'Value' method.

Appendix B

Lite Communications Control

This appendix contains a list of the available component properties and gives details of the Visual Basic script interface. These properties can be set in run time by using a Visual Basic script command – for example: -

```
OMRONCXCommunicationsControl1.ServerNodeName = "\\NAME"
```

The Script Interface defines the Visual Basic script interface for the Lite communications control. See ExecuteVBScript script functions for more information on running Visual Basic Script.

Component Properties

Property Title	Example	Description
DisplayErrors	True False	When set True, the object will display a message box for any errors. If set to False, error messages are not displayed.
ListPLCs		Holds a list of all PLC names configured in the project file. This property is read only.
ListPoints		Holds a list of all point names configured in the project file. This property is read only.

Script Interface

The Script Interface defines the Visual Basic script interface for the Lite communications control.

Functions

Value	Function for getting and setting an area of memory in a PLC. This function allows logical names to be used. If an array is used, the first element is returned.
Values	Function for getting and setting an area of memory in a PLC. This function allows logical names to be used. If an array is used then a SAFEARRAY is returned with all values.
SetDefaultPLC	Function for setting the default PLC. This is primarily used when a project contains multiple PLCs.
OpenPLC	Opens the specific PLC for communications.
ClosePLC	Closes the specific PLC.
ReadArea	Function for reading a block of memory from the PLC.
WriteArea	Function for writing a block of memory to the PLC.
RunMode	Function for reading / writing the current mode of the PLC.
TypeName	Function for reading the PLC type (e.g. CQM1H).
IsPointValid	Checks a point name is valid.
PLC Memory Functions	A, AR, C, CIO, D, DM, DR, E, EM, G, GR, H, IR, LR, SR, ST, T, TC, TK, W. Functions for getting and setting the memory areas in the PLC.

Value

Reads the value of an address from a PLC, or writes a value to an address in a PLC. This function allows logical names.

Example 1 – Reading a value from the PLC using a logical name.

```
intVal = OMRONCXCommunicationsControl1.Value("BoilerTemp")  
or  
intVal = OMRONCXCommunicationsControl1 ("BoilerTemp")
```

In these examples, the PLC address associated with 'BoilerTemp' will be read from the PLC and stored in 'intVal'. "Value" is the default property and does not have to be specified.

Example 2 – Writing a value to the PLC using a logical name.

```
OMRONCXCommunicationsControl1.Value("BoilerTemp") = 50  
or  
OMRONCXCommunicationsControl1 ("BoilerTemp") = 50
```

In these examples, the value 50 will be written to the PLC address associated with 'BoilerTemp'. "Value" is the default property and does not have to be specified.

Further examples

```
OMRONCXCommunicationsControl1 ("PLCName/DM0") = 1000  
OMRONCXCommunicationsControl1 ("DM0") = 1000  
intVal = CommunicationsControl1("DM100")
```

These examples are physical addresses. A PLC name can optionally be specified otherwise the current default PLC will be assumed.

Values

Reads an array of values from a PLC, or writes an array of values to a PLC. This function allows logical names. If an array is used then a SAFEARRAY is returned with all values.

Example 1 – Reading an array of values from the PLC using a logical name.

```
SomeArray = OMRONCXCommunicationsControl1.Values("BoilerTemps")
```

Example 2 – Writing an array of values to the PLC using a logical name.

```
OMRONCXCommunicationsControl1.Values("BoilerTemps") = SomeArray
```

SetDefaultPLC

The 'SetDefaultPLC' function can be used to inform the script parser that a particular PLC is has been set as the default. Once a default PLC has been set, then it is not necessary (with some functions) to specify a PLC name. For example,

```
OMRONCXCommunicationsControl1.SetDefaultPLC("MyPLC")  
intVal = OMRONCXCommunicationsControl1.Value("BoilerTemp1")  
OMRONCXCommunicationsControl1.Value("BoilerTemp1") = 75  
intVal = OMRONCXCommunicationsControl1.Value("DM50")
```

Each 'Value' function above will access data in the PLC called 'MyPLC'.

Note: If there is only 1 PLC in the project then it is not necessary to call the 'SetDefaultPLC' function. The first PLC in a project will automatically be set as the default PLC.

OpenPLC

Opens a PLC for communications. If no PLC is specified then the default PLC is opened.

Example 1:

```
OMRONCXCommunicationsControl1.SetDefaultPLC("MyPLC")
OMRONCXCommunicationsControl1.OpenPLC()
OMRONCXCommunicationsControl1.DM(100) = 10
OMRONCXCommunicationsControl1.DM(50) = 10
```

Example 2:

```
OMRONCXCommunicationsControl1.OpenPLC("MyPLC")
OMRONCXCommunicationsControl1.DM(100) = 10
```

ClosePLC

Closes a previously opened PLC. If no PLC is specified then the default PLC is closed.

Example:

```
OMRONCXCommunicationsControl1.ClosePLC("MyPLC")
```

ReadArea

Reads a specified block of memory from a PLC.

Examples of synchronous read:

```
MyVariant = OMRONCXCommunicationsControl1.ReadArea("MyPLC/DM0", 12, vbString)
MyVariant = OMRONCXCommunicationsControl1.ReadArea("BoilerTemp", 10, vbInteger)
MyVariant = OMRONCXCommunicationsControl1.ReadArea("BoilerTemp", 20)
```

In the first example, DM0 to DM11 will be read as characters (part of a string) from 'MyPLC' and will be stored in 'MyVariant'. The second example demonstrates that it is also possible to use a logical name for the start address, and that any VB variant types (such as vbInteger) can be used. The third example shows that the VB Variant type parameter is optional – if none is specified then vbInteger is assumed. The script will wait for the read operation to complete before continuing to execute the next line.

WriteArea

Writes a block of memory to a specified area in a PLC.

Examples of synchronous write:

```
MyString = "TestString"
OMRONCXCommunicationsControl1.WriteArea "MyPLC/DM50", 10, MyString
Dim newValue(2) As Long
newValue(1) = 0
newValue(2) = 1
OMRONCXCommunicationsControl1.WriteArea "BoilerTemp",2,newValue
```

In the first example, the contents of 'MyString' will be written into DM50 to DM54. Any additional data in 'MyString' will be ignored (i.e. if 'MyString' is 15 characters in length then the first 10 characters will be written to DM50 to DM54 and the remaining 5 characters will be ignored – {Note: each PLC address holds 2 characters}). The second example shows that a logical name can be used. The script will wait for the write operation to complete before continuing to execute the next line.

RunMode

Reads the current operating mode of a PLC (Stop/Program, Debug, Monitor, Run), where 0=Stop/Program mode, 1=Debug mode, 2=Monitor mode and 4=Run mode.

Example

```
intMode = OMRONCXCommunicationsControl1.RunMode("MyPLC")
```

In this example, the operating mode would be read from 'MyPLC' and stored in 'intMode'. If 'MyPLC' was in 'Monitor' mode then 'intMode' would be set to the value 2.

TypeName

Reads the PLC model name of a PLC (e.g. C200H, CQM1H, CVM1 etc).

Example

```
strPLCType = OMRONCXCommunicationsControl1.TypeName("MyPLC")
```

In this example, the PLC model type will be read from 'MyPLC' and will be stored in 'strPLCType'.

IsPointValid

Checks if a Point name has been defined in the CX-Server project file.

Examples

```
bValid = OMRONCXCommunicationsControl1.IsPointValid("MyPoint")
```

```
bValid = OMRONCXCommunicationsControl1.IsPointValid("MyPoint", "MyPLC")
```

In both examples, the boolean variable *bValid* is set True if the point "MyPoint" has been defined.

PLC Memory Functions

(A, AR, C, CIO, D, DM, DR, E, EM, - G, GR, H, IR, LR, SR, ST, T, TC, TK, W)

All PLC memory functions (e.g. A, AR, D, DM etc.) work in exactly the same way. The following examples use the DM function to get and set the value of a DM address in a PLC.

Example 1

```
intVal = OMRONCXCommunicationsControl1.DM(100)
```

In this example, the contents of DM100 will be read from the PLC and stored in 'intVal'.

Note: These examples assume there is only 1 PLC in the CX-Server project file, or that the 'SetDefaultPLC' function has been used to select the required PLC. Refer to the 'SetDefaultPLC' function for details about using script with multiple PLCs in the project.

Example 2

OMRONCXCommunicationsControl1.DM(100) = 75

In this example, the value 75 will be written to DM100 in the PLC.

Bit addressing, that is accessing data from individual memory bits, is also supported by these memory areas: IR, AR, HR and CIO.

Example 3

bVal = OMRONCXCommunicationsControl1.IR("100.2")

In this example, the status of bit IR100.2 (i.e. bit 2 of IR100) will be read from the PLC and stored in 'bVal' (e.g. 'bVal' will be set to TRUE or FALSE).

Example 4

OMRONCXCommunicationsControl1.IR("100.2") = True

In this example, bit IR100.2 (i.e. bit 2 of IR100) in the PLC will be set to True. Note that use of the quotes is optional, but is required to differentiate between 100.1 and 100.10

APPENDIX C

VBScript Features

This appendix provides a summary of VBScript features available for use with the ExecuteVBScript and ExecuteVBScriptFile script functions. These features are provided by the Windows Scripting Host, included by default with Windows 98 and Windows 2000 and many Microsoft products including Internet Explorer 5. For Windows 95 and Windows NT, the Windows Scripting Host is available as a free download from Microsoft's Web site.

For details of the latest versions and support see the Microsoft website at – <http://msdn.microsoft.com/scripting>.

Category	Keyword / Feature
Array handling	Array Dim, Private, Public, ReDim IsArray Erase LBound, UBound
Assignments	Set
Comments	Comments using ' or Rem
Constants/Literals	Empty Nothing Null True, False

GLOSSARY OF TERMS

AND A logic operator used to interrogate Boolean type points. AND returns 'TRUE' if all arguments are 'TRUE'. An example of AND is that if *a* is a statement and *b* is a statement, AND returns 'TRUE' if both *a* and *b* are 'TRUE'. If one or both statements return 'FALSE' then AND returns 'FALSE'.

Application A software program that accomplishes a specific task. Examples of applications are CX-Supervisor, SYSMAC-CDM, Microsoft Word for Windows and Microsoft Excel. CX-Supervisor and its development environment allows the creation and testing of new applications through a Graphical User Interface (GUI).

Arguments Words, phrases, or numbers that can be entered on the same line as a command or statement to expand or modify the command or statement within the CX-Supervisor script language. The command acts on the argument. In essence the command is a *verb*, and the argument is the *object of the verb*. An example of an argument in CX-Supervisor is "DDETerminate(channel)" where DDETerminate is a command within the script language, and channel is the argument upon which the command will act.

Bitmap The representation of an image stored in a computer's memory. Each picture element (pixel) is represented by bits stored in the memory. In CX-Supervisor a bitmap image can be installed as a single object.

Boolean type A type of point where the value of the point can be one of two states. Essentially the two states are '0' and '1', but these states can be assigned a meaningful designation. Examples are:

State	Example	Example	Example	Example
0	'OFF'	'FALSE'	'OUT'	'CLOSED'
1	'ON'	'TRUE'	'IN'	'OPEN'

See also: **AND**, **NOT** and **OR**.

Communications Driver The relevant communications management system for OMRON PLCs in conjunction with Microsoft Windows, providing facilities for other SYSMAC software to maintain PLC device and address information and to communicate with OMRON PLCs and their supported network types.

Constant Within CX-Supervisor, a constant is a point within the script language that takes only one specific value.

Control Object In CX-Supervisor, a control object is applied in the development environment and can be a pushbutton, a toggle button, a slider, a trend graph, a rotational gauge or a linear gauge. Essentially a control object can be a complex graphic object consisting of a number of primitive graphic objects, which provides user interaction.

Database Connection Level	<p>A Database Connection Level is a string which determines what level in the database tree hierarchy is to be operated on. Some examples are listed below:</p> <table border="0"> <tr> <td>"Northwind"</td> <td>Connectionlevel</td> </tr> <tr> <td>"CSV.Result"</td> <td>Recordset level</td> </tr> <tr> <td>"Northwind.Order Details.OrderID"</td> <td>Field level</td> </tr> <tr> <td>"Invoice.Data Types"</td> <td>Schema level</td> </tr> </table>	"Northwind"	Connectionlevel	"CSV.Result"	Recordset level	"Northwind.Order Details.OrderID"	Field level	"Invoice.Data Types"	Schema level
"Northwind"	Connectionlevel								
"CSV.Result"	Recordset level								
"Northwind.Order Details.OrderID"	Field level								
"Invoice.Data Types"	Schema level								
DDE	<p>Dynamic Data Exchange. A channel through which correctly prepared programs can actively exchange data and control other applications within Microsoft Windows. CX-Supervisor, through the use of its script language, allows extensive use of DDE functionality.</p>								
Development Environment	<p>SCADA applications are created and tested using the development environment within CX-Supervisor. On completion, the finished application can be delivered as a final customer application to be run by the run-time environment.</p>								
DLL	<p>Dynamic Link Library. A program file that although cannot be run stand-alone as an executable, can be utilised by one or more applications or programs as a common service. DLL files have a *.DLL extension. DLL's comprise a number of stand-alone functions. In CX-Supervisor, a DLL containing icons can be accessed to represent the display part of an OLE object. One such DLL, 'MORICONS.DLL', is provided in the standard Microsoft Windows installation.</p>								
Download	<p>A recipe is <i>downloaded</i> during runtime. This process involves identifying the appropriate recipe and executing the validation code, if any exists. The download is complete when each ingredient has set its point to the target value.</p>								
Embedded Object	<p>An embedded object is a complex object that can be a bitmap object or an OLE object.</p>								
Executable	<p>A file that contains programs or commands of an application that can be executed by a user or another application. Executable files have a *.EXE file extension. CX-Supervisor provides two executable files, one for the development environment (CX-SUPERVISORDEV.EXE), and one for the run-time environment (SCS.EXE).</p>								
Expressions	<p>In the CX-Supervisor script language, expressions are a construct for computing a value from one or more operands. For instance, in the example "lift = height + rate", the expression is "height + rate" where the result yielded from the expression is used for the value of "lift". Outside of the script language, expressions consisting of operators and operands can be used to control objects, through actions.</p>								
Graphic Object	<p>In CX-Supervisor, a graphic object is created in the development environment, and can be a line, an arc, a polygon (including a square and rectangle), a round rectangle, an ellipse (including a circle), or a polyline. A complex object can exist as a combination of two or more graphic objects.</p>								

GUI	Graphical User Interface. Part of a program that interacts with the user and takes full advantage of the graphics displays of computers. A GUI employs pull-down menus and dialog boxes for ease of use. Like all Microsoft Windows based applications, CX-Supervisor has a GUI.
I / O type	Input / Output type. An attribute of a point that defines the origin and destination of the data for that point. The data for a point can originate (be <i>input</i> from) and is destined (is <i>output</i> to) to the internal computer memory, PLC, DDE target application.
Icon	Pictorial representations of computer resources and functions. The CX-Supervisor development environment and run-time environment are run from icons. Icons are also used in CX-Supervisor to indicate an OLE object.
Ingredient	Each recipe consists of at least one ingredient. Each ingredient must be related to an existing point.
Integer type	A type of point where the value of the point can only be a whole positive or negative number.
Item	Within the CX-Supervisor script language, Item is used in DDE functions to contain specific information pertaining to an outside application. Using DDE functions, CX-Supervisor allows the manipulation of an outside application with the target application command contained within Item.
Microsoft Excel	A spreadsheet application.
Microsoft Windows	<p>A windowing environment for MS-DOS computers, that is noted for its GUI, and for features such as multiple typefaces, desk accessories (such as a clock, calculator, calendar and notepad), and the capability of moving text and graphics from one application to another via a clipboard.</p> <p>CX-Supervisor will run only under Microsoft Windows. DDE functions communicating with other applications supported by CX-Supervisor use Microsoft Windows as a basis.</p>
Microsoft Word for Windows	<p>A word processing application.</p> <p>See also SVGA mode and VGA mode.</p>
Nesting	To incorporate one or more IF THEN ELSE/ELSEIF ENDIF statements inside a structure of the same kind.
Network	<ol style="list-style-type: none">1. Part of the PLC configuration, based on the device type. The number of Networks available is dependant on the device type.2. A number of computers linked together with a central processing point known as a Server which is accessible to all computers. Networks affect CX-Supervisor in that further Network associated options are available if the computer is Network connected.
Non-Volatile	A point that is designated as 'non-volatile' is a point whose value is saved on disk and automatically reloaded when CX-Supervisor resumes execution.

NOT	A logic operator used to interrogate Boolean type points which produces the Boolean inverse of the supplied argument. An example of NOT is that if <i>a</i> is a statement and is 'FALSE', then NOT returns 'TRUE'. If <i>a</i> is a statement and is 'TRUE', then NOT returns 'FALSE'.
Object	In CX-Supervisor, an object can be text, graphics, a control, a bitmap, or OLE object as created in the development environment. A complex object can exist as a combination of two or more objects of any of the above types. Specifically, graphical objects can be categorised as a line, an arc, a polygon (including a square and rectangle), a round rectangle, an ellipse (including a circle), or a polyline. A control is essentially a complex graphic object and is specifically either a pushbutton, a toggle button, a slider, a trend graph, a rotational gauge or a linear gauge.
OLE	Object Linking and Embedding. Used to transfer and share information between Microsoft Windows based applications and accessories. When OLE is used in CX-Supervisor, it is possible to view or even edit a file from a target application.
Operand	The term used for constants or point variables.
Operator	A symbol used as a function, with infix syntax if it has two arguments (e.g. "+") or prefix syntax if it has only one argument (e.g. NOT). The CX-Supervisor script language uses operators for built-in functions such as arithmetic and logic.
OR	A logic operator used to interrogate Boolean type points. OR returns 'TRUE' if any of the supplied arguments are 'TRUE'. An example of OR is that if <i>a</i> is a statement and <i>b</i> is a statement, OR will return 'TRUE' if either <i>a</i> and <i>b</i> are 'TRUE'. If both statements return 'FALSE' then OR will return 'FALSE'.
Pages	The combination and manipulation of pages containing objects within projects forms the basis of CX-Supervisor. More than one page can exist for each project. The pages in a project provide the visual aspect of CX-Supervisor corresponding to a display with the objects contained in each page providing a graphical representation of the system being monitored.
Pixel	A single displayable point on the screen from which a displayed image is constructed. The screen resolution of the computer's Visual Display Unit (VDU) is defined by the number of pixels across and the number of pixels down (e.g. 1024 x 768).
PLC	Programmable Logic Controller.
Point variable	A point within the CX-Supervisor script language that stores a value or string assigned to that point.
Point	A point is used to hold a value of a predefined type - Boolean, Integer, Text, etc. The contents of a point may be controlled by an object or I/O mechanism such as DDE. The contents of a point may control the action or appearance of an object, or be used for output via an I/O mechanism.

Program Manager	An integral part of Microsoft Windows 3.x which allows Microsoft Windows based applications to be started from icons and for all applications to be organised. CX-Supervisor can be run from Program Manager.
Project	<p>A CX-Supervisor application will consist of one or a number of pages linked together. The pages may contain passive or active graphics, text or animations, and may be grouped together logically to form a project. A project may consist of many pages, or simply a single page. Projects may be built and tested within the CX-Supervisor development environment, and run stand-alone under the CX-Supervisor run-time environment.</p> <p>Only one project at a time may be open for editing within the CX-Supervisor development environment.</p>
Real type	A type of point where the value of the point can be any number, including those containing a decimal point.
Recipe	A recipe is a set of pre-defined steps used to perform a particular task. A CX-Supervisor project may contain zero or more number of recipes. Recipes are defined in the development environment and executed, or downloaded, in the run-time environment.
Run Time Environment	SCADA applications are run using the run-time environment of CX-Supervisor, following creation of the application in the CX-Supervisor development environment.
SCADA	Supervisory Control and Data Acquisition. (see CX-Supervisor)
Server	<ol style="list-style-type: none">1. Within the CX-Supervisor script language, Server is used in DDE functions to contain a link to an outside application. Using DDE functions, CX-Supervisor allows the manipulation of an outside application as specified as the Server. See also Server Application.2. A Server is the central processing point of a Network which is accessible to all computers. Networks affect CX-Supervisor in that further associated options are available if the computer Network is connected.
Server Application	<p>An application that can be used to view or interact with, whilst currently within CX-Supervisor.</p> <p>See also DDE and OLE.</p>
Statement	Within the CX-Supervisor script language, a statement is a command understood by the run-time environment. Statements are constructed of commands and arguments, which when combined, help to formulate a finished application to be used in the run-time environment.
String	The contents of a Text type point that can only contain literal alphanumeric characters. A string starts following an opening quotation mark, and ends before a closing question mark; in the example "name = "spot", the point "name" holds the string spot.

SVGA mode	A mode of video display that provides 800 × 600 pixel resolution (or higher) with 16 or more colours and is supported on Super Video Graphics Adapter systems.
CX-Supervisor	A SCADA software application which creates and maintains graphical user interfaces and communicates with PLCs and other I/O mechanisms.
Target Value	An ingredient must specify a target value for its related point. This is the value to which the point will be set in runtime when the recipe is downloaded.
Text Object	In CX-Supervisor, a text object is a string on a page. Attributes such as typeface, point size, embolden, italicise, underline, left justify, flush right, and centre can be applied to enhance its presentation.
Text type	A type of point that holds a string.
Topic	Within the CX-Supervisor script language, Topic is used in DDE functions to specify a file name pertaining to an outside application. Using DDE functions, CX-Supervisor allows the opening of a file, part of the server application.
Validation Code	Recipe validation code is CX-Supervisor script language which is used to check point values before downloading a recipe.
VGA mode	A mode of video display that provides 640 × 480 pixel resolution with 16 colours and is supported on Video Graphics Adapter systems.
Windows Desktop	An integral part of Microsoft Windows which allows Microsoft Windows based applications to be started from icons and for all applications to be organised. CX-Supervisor can be run from Windows Desktop.
Wizard	Wizards are dialogs used by the CX-Supervisor development environment to take the user through complex operations in a simplified step-by-step process.
